Table of Contents

About.....	1
Chapter 1: Getting started with Objective-C Language.....	2
Versions.....	2
Examples.....	2
Hello World.....	2
Compiling the program.....	3
Chapter 2: Basic Data Types.....	4
Syntax.....	4
Examples.....	4
BOOL.....	4
id.....	4
SEL.....	5
IMP (implementation pointer).....	6
NSInteger and NSUInteger.....	7
Chapter 3: Blocks.....	9
Syntax.....	9
Remarks.....	9
Examples.....	9
Blocks as Method Parameters.....	9
Defining and Assigning.....	10
Blocks as Properties.....	10
Block Typedefs.....	10
Blocks as local variables.....	11
Chapter 4: BOOL / bool / Boolean / NSCFBoolean.....	12
Examples.....	12
BOOL/Boolean/bool/NSCFBoolean.....	12
BOOL VS Boolean.....	12
Chapter 5: Categories.....	14
Syntax.....	14
Remarks.....	14

Examples.....	14
Simple Category.....	14
Declaring a class method.....	14
Adding a property with a category.....	15
Conforming to protocol.....	15
Create a Category on XCode.....	16
Chapter 6: Classes and Objects.....	19
Syntax.....	19
Examples.....	19
Creating classes with initialization values.....	19
Singleton Class.....	19
The "instancetype" return type.....	21
Specifying Generics.....	21
Difference between allocation and initialization.....	22
Chapter 7: Continue and Break!.....	23
Examples.....	23
Continue and Break Statement.....	23
Chapter 8: Declare class method and instance method.....	25
Introduction.....	25
Syntax.....	25
Examples.....	25
How to declare class method and instance method.....	25
Chapter 9: Enums.....	27
Syntax.....	27
Examples.....	27
Defining an enum.....	27
typedef enum declaration in Objective-C.....	27
Converting C++ std::vector to an Objective-C Array.....	28
Chapter 10: Error Handling.....	30
Syntax.....	30
Examples.....	30
Asserting.....	30

Error & Exception handling with try catch block.....	30
Chapter 11: Fast Enumeration.....	32
Examples.....	32
Fast enumeration of an NSArray.....	32
Fast enumeration of an NSArray with index.....	32
Chapter 12: Format-Specifiers.....	33
Introduction.....	33
Syntax.....	33
Remarks.....	33
Examples.....	34
Integer Example - %i.....	34
Chapter 13: Grand Central Dispatch.....	35
Introduction.....	35
Examples.....	35
What is Grand central dispatch.....	35
Chapter 14: Inheritance.....	36
Syntax.....	36
Examples.....	36
Car is inherited from Vehicle.....	36
Chapter 15: Key Value Coding / Key Value Observing.....	38
Examples.....	38
Most Common Real Life Key Value Coding Example.....	38
Key Value Observing.....	38
Querying KVC Data.....	40
Collection Operators.....	40
Chapter 16: Logging.....	44
Syntax.....	44
Remarks.....	44
Examples.....	44
Logging.....	44
NSLog vs printf.....	44

NSLog Output Format	45
Logging Variable Values	45
Empty message is not printed	45
Removing Log Statements from Release Builds	46
Using __FUNCTION__	46
NSLog and BOOL type	46
Logging NSLog meta data	47
Logging by Appending to a File	47
Chapter 17: Low-level Runtime Environment	49
Remarks	49
Examples	49
Attach object to another existing object (association)	49
Augmenting methods using Method Swizzling	49
Calling methods directly	51
Chapter 18: Memory Management	53
Examples	53
Automatic Reference Counting	53
Strong and weak references	54
Manual Memory Management	54
Memory management rules when using manual reference counting	55
Chapter 19: Methods	57
Syntax	57
Examples	57
Method parameters	57
Create a basic method	57
Return values	58
Class methods	58
Calling methods	58
Instance methods	59
Pass by value parameter passing	59
Pass by reference parameter passing	60
Chapter 20: Modern Objective-C	62

Examples.....	62
Literals.....	62
NSNumber.....	62
NSArray.....	62
NSDictionary.....	62
Container subscripting.....	63
Chapter 21: Multi-Threading.....	64
Examples.....	64
Creating a simple thread.....	64
Create more complex thread.....	64
Thread-local storage.....	65
Chapter 22: NSArray.....	66
Syntax.....	66
Examples.....	66
Creating Arrays.....	66
Finding out the Number of Elements in an Array.....	66
Accessing elements.....	66
Getting a single item.....	66
First and Last Item.....	67
Filtering Arrays With Predicates.....	67
Converting NSArray to NSMutableArray to allow modification.....	67
Sorting array with custom objects.....	67
Compare method.....	67
NSSortDescriptor.....	68
Blocks.....	68
Performance.....	68
Converting between Sets and Arrays.....	68
Reverse an Array.....	68
Looping through.....	69
Using Generics.....	69
Enumerating using blocks.....	69
Comparing arrays.....	70

Add objects to NSArray.....	70
Chapter 23: NSArray.....	71
Examples.....	71
Creating NSArray instances.....	71
Sorting Arrays.....	71
Filter NSArray and NSMutableArray.....	71
Chapter 24: NSAttributedString.....	73
Examples.....	73
Creating a string that has custom kerning (letter spacing) editshare.....	73
Create a string with text struck through.....	73
Using Enumerating over Attributes in a String and underline part of string.....	73
How you create a tri-color attributed string.....	74
Chapter 25: NSCache.....	75
Examples.....	75
NSCache.....	75
Chapter 26: NSCalendar.....	76
Examples.....	76
System Locale Information.....	76
Initializing a Calendar.....	76
Calendrical Calculations.....	77
Chapter 27: NSData.....	78
Examples.....	78
Create.....	78
Get NSData length.....	78
Encoding and decoding a string using NSData Base64.....	78
NSData and Hexadecimal String.....	79
Chapter 28: NSDate.....	81
Remarks.....	81
Examples.....	81
Creating an NSDate.....	81
Date Comparison.....	81
Convert NSDate that is composed from hour and minute (only) to a full NSDate.....	82

Converting NSDate to NSString.....	83
Chapter 29: NSDictionary.....	84
Examples.....	84
Create.....	84
NSDictionary to NSArray.....	84
NSDictionary to NSData.....	84
NSDictionary to JSON.....	85
Block Based Enumeration.....	85
Fast Enumeration.....	85
Chapter 30: NSDictionary.....	86
Syntax.....	86
Remarks.....	86
Examples.....	86
Creating using literals.....	86
Creating using dictionaryWithObjectsAndKeys:.....	86
Creating using plists.....	87
Setting a Value in NSDictionary.....	87
Standard.....	87
Shorthand.....	87
Getting a Value from NSDictionary.....	87
Standard.....	88
Shorthand.....	88
Check if NSDictionary already has a key or not.....	88
Chapter 31: NSJSONSerialization.....	89
Syntax.....	89
Parameters.....	89
Remarks.....	89
Examples.....	89
JSON Parsing using NSJSONSerialization Objective c.....	89
Chapter 32: NSMutableArray.....	91
Examples.....	91
Adding elements.....	91

Insert Elements.....	91
Deleting Elements.....	91
Sorting Arrays.....	92
Move object to another index.....	92
Filtering Array content with Predicate.....	92
Creating an NSMutableArray.....	92
Chapter 33: NSMutableDictionary.....	94
Parameters.....	94
Examples.....	94
NSMutableDictionary Example.....	94
Removing Entries From a Mutable Dictionary.....	95
Chapter 34: NSObject.....	97
Introduction.....	97
Syntax.....	97
Examples.....	97
NSObject.....	97
Chapter 35: NSPredicate.....	99
Syntax.....	99
Remarks.....	99
Examples.....	99
Filter By Name.....	99
Find movies except given ids.....	100
Find all the objects which is of type movie.....	101
Find Distinct object ids of array.....	101
Find movies with specific ids.....	101
Case Insensitive comparison with exact title match.....	101
Case sensitive with exact title match.....	101
Case Insensitive comparison with matching subset.....	101
Chapter 36: NSRegularExpression.....	102
Syntax.....	102
Examples.....	102
Find all the numbers in a string.....	102

Check whether a string matches a pattern.....	102
Chapter 37: NSSortDescriptor.....	104
Examples.....	104
Sorted by combinations of NSSortDescriptor.....	104
Chapter 38: NSString.....	105
Introduction.....	105
Remarks.....	105
Examples.....	105
Creation.....	105
String Length.....	106
Changing Case.....	106
Comparing Strings.....	106
Joining an Array of Strings.....	107
Encoding and Decoding.....	107
Splitting.....	108
Searching for a Substring.....	109
Working with C Strings.....	109
Removing Leading and Trailing Whitespace.....	110
Formatting.....	110
Reversing a NSString Objective-C.....	110
Chapter 39: NSTextAttachment.....	112
Syntax.....	112
Remarks.....	112
Examples.....	112
NSTextAttachment Example.....	112
Chapter 40: NSTimer.....	113
Examples.....	113
Creating a Timer.....	113
Invalidating a timer.....	113
Manually firing a timer.....	113
Storing information in the Timer.....	114
Chapter 41: NSURL.....	115

Examples.....	115
Create.....	115
Compare NSURL.....	115
Modifying and Converting a File URL with removing and appending path.....	115
Chapter 42: NSURL send a post request.....	117
Examples.....	117
Simple POST request.....	117
Simple Post Request With Timeout.....	117
Chapter 43: UserDefaults.....	118
Examples.....	118
Simple example.....	118
Clear UserDefaults.....	118
Chapter 44: Predefined Macros.....	119
Introduction.....	119
Syntax.....	119
Examples.....	119
Predefined Macros.....	119
Chapter 45: Properties.....	120
Syntax.....	120
Parameters.....	120
Examples.....	121
What are properties?.....	121
Custom getters and setters.....	122
Properties that cause updates.....	123
Chapter 46: Protocols.....	126
Examples.....	126
Basic Protocol Definition.....	126
Optional and required methods.....	126
Conforming to Protocols.....	126
Forward Declarations.....	127
Checking existance of optional method implementations.....	127
Check conforms Protocol.....	127

Chapter 47: Protocols and Delegates	129
Remarks	129
Examples	129
Implementation of Protocols and Delegation mechanism	129
Chapter 48: Random Integer	131
Examples	131
Basic Random Integer	131
Random Integer within a Range	131
Chapter 49: Singletons	132
Introduction	132
Examples	132
Using Grand Central Dispatch (GCD)	132
Creating Singleton class and also preventing it from having multiple instances using alloc	132
Creating Singleton and also preventing it from having multiple instance using alloc/init,	133
Chapter 50: Structs	135
Syntax	135
Remarks	135
Examples	135
CGPoint	135
Defining a Structure and Accessing Structure Members	136
Chapter 51: Subscripting	138
Examples	138
Subscripts with NSArray	138
Subscripts with NSDictionary	138
Custom Subscripting	139
Chapter 52: Unit testing using Xcode	140
Remarks	140
Examples	140
Testing a block of code or some method:	141
Feed the dummy data to the method under test if required & then compare the expected & act	141
Testing asynchronous block of code:	141

Measuring Performance of a block of code:.....	141
Running Test Suits:.....	142
Note:.....	142
Chapter 53: XML parsing	144
Examples.....	144
XML Parsing.....	144
Credits	146

About

You can share this PDF with anyone you feel could benefit from it, downloaded the latest version from: [objective-c-language](#)

It is an unofficial and free Objective-C Language ebook created for educational purposes. All the content is extracted from [Stack Overflow Documentation](#), which is written by many hardworking individuals at Stack Overflow. It is neither affiliated with Stack Overflow nor official Objective-C Language.

Chapter 1: Getting started with Objective-C Language

Versions

Version	Release Date
1.0	1983-01-01
2.0	2007-10-27
Modern	2014-03-10

Examples

Hello World

This program will output "Hello World!"

```
#import <Foundation/Foundation.h>

int main(int argc, char * argv[]) {
    NSLog(@"Hello World!");
}
```

`#import` is a pre-processor directive, which indicates we want to *import* or include the information from that file into the program. In this case, the compiler will copy the contents of `Foundation.h` in the `Foundation` framework to the top of the file. The main difference between `#import` and `#include` is that `#import` is "smart" enough to not reprocess files that have already been included in other `#includes`.

The [C Language documentation](#) explains the `main` function.

The `NSLog()` function will print the string provided to the console, along with some debugging information. In this case, we use an Objective-C string literal: `@"Hello World!"`. In C, you would write this as `"Hello World!"`, however, Apple's Foundation Framework adds the `NSString` class which provides a lot of useful functionality, and is used by `NSLog`. The simplest way to create an instance of `NSString` is like this: `@"string content here"`.

Technically, `NSLog()` is part of Apple's Foundation Framework and is not actually part of the Objective-C language. However, the Foundation Framework is ubiquitous throughout Objective-C programming. Since the Foundation Framework is not open-source and cannot be used outside of Apple development, there are open-source alternatives to the framework which are associated with [OPENStep](#) and [GNUStep](#).

Compiling the program

Assuming we want to compile our Hello World program, which consist of a single `hello.m` file, the command to compile the executable is:

```
clang -framework Foundation hello.m -o hello
```

Then you can run it:

```
./hello
```

This will output:

```
Hello World!
```

The options are:

- `-framework`: Specifies a framework to use to compile the program. Since this program uses Foundation, we include the Foundation framework.
- `-o`: This option indicate to which file we'd like to output our program. In our case `hello`. If not specified, the default value is `a.out`.

Read [Getting started with Objective-C Language online](https://riptutorial.com/objective-c/topic/199/getting-started-with-objective-c-language): <https://riptutorial.com/objective-c/topic/199/getting-started-with-objective-c-language>

Chapter 2: Basic Data Types

Syntax

- `BOOL havePlutonium = YES;` // Direct assignment
- `BOOL fastEnough = (car.speedInMPH >= 88);` // Comparison expression
- `BOOL fluxCapacitorActive = (havePlutonium && fastEnough);` // Boolean expression
-
- `id somethingWicked = [witchesCupboard lastObject];` // Retrieve untyped object
- `id powder = prepareWickedIngredient(somethingWicked);` // Pass and return
- `if ([ingredient isKindOfClass:[Toad class]]) {` // Test runtime type

Examples

BOOL

The `BOOL` type is used for boolean values in Objective-C. It has two values, `YES`, and `NO`, in contrast to the more common "true" and "false".

Its behavior is straightforward and identical to the C language's.

```
BOOL areEqual = (1 == 1);    // areEqual is YES
BOOL areNotEqual = !areEqual // areNotEqual is NO
NSAssert(areEqual, "Mathematics is a lie"); // Assertion passes

BOOL shouldFlatterReader = YES;
if (shouldFlatterReader) {
    NSLog(@"Only the very smartest programmers read this kind of material.");
}
```

A `BOOL` is a primitive, and so it cannot be stored directly in a Foundation collection. It must be wrapped in an `NSNumber`. Clang provides special syntax for this:

```
NSNumber * yes = @YES;    // Equivalent to [NSNumber numberWithInt:YES]
NSNumber * no = @NO;      // Equivalent to [NSNumber numberWithInt:NO]
```

The `BOOL` implementation is directly based on C's, in that it is a typedef of the C99 standard type `bool`. The `YES` and `NO` values are defined to `__objc_yes` and `__objc_no`, respectively. These special values are compiler builtins introduced by Clang, which are translated to `(BOOL)1` and `(BOOL)0`. If they are not available, `YES` and `NO` are defined directly as the cast-integer form. The definitions are found in the Objective-C runtime header `objc.h`

id

`id` is the generic object pointer, an Objective-C type representing "any object". An instance of any Objective-C class can be stored in an `id` variable. An `id` and any other class type can be assigned

back and forth without casting:

```
id anonymousSurname = @"Doe";
NSString * surname = anonymousSurname;
id anonymousFullName = [NSString stringWithFormat:@"%@", John", surname];
```

This becomes relevant when retrieving objects from a collection. The return types of methods like `objectAtIndex:` are `id` for exactly this reason.

```
DataRecord * record = [records objectAtIndex:anIndex];
```

It also means that a method or function parameter typed as `id` can accept any object.

When an object is typed as `id`, any known message can be passed to it: method dispatch does not depend on the compile-time type.

```
NSString * extinctBirdMaybe =
    [anonymousSurname stringByAppendingString:anonymousSurname];
```

A message that the object does not actually respond to will still cause an exception at runtime, of course.

```
NSDate * nope = [anonymousSurname addTimeInterval:10];
// Raises "Does not respond to selector" exception
```

Guarding against exception.

```
NSDate * nope;
if([anonymousSurname isKindOfClass:[NSDate class]]){
    nope = [anonymousSurname addTimeInterval:10];
}
```

The `id` type is defined in `objc.h`

```
typedef struct objc_object {
    Class isa;
} *id;
```

SEL

Selectors are used as method identifiers in Objective-C.

In the example below, there are two selectors. `new` and `setName:`

```
Person* customer = [Person new];
[customer setName:@"John Doe"];
```

Each pair of brackets corresponds to a message send. On the first line we send a message

containing the `new` selector to the `Person` class and on the second line we send a message containing the `setName:` selector and a string. The receiver of these messages uses the selector to look up the correct action to perform.

Most of the time, message passing using the bracket syntax is sufficient, but occasionally you need to work with the selector itself. In these cases, the `SEL` type can be used to hold a reference to the selector.

If the selector is available at compile time, you can use `@selector()` to get a reference to it.

```
SEL s = @selector(setName:);
```

And if you need to find the selector at runtime, use `NSStringFromClass`.

```
SEL s = NSSelectorFromString(@"setName:");
```

When using `NSSelectorFromString`, make sure to wrap the selector name in a `NSString`.

It is commonly used to check if a delegate implements an optional method.

```
if ([self.myDelegate respondsToSelector:@selector(doSomething)]) {  
    [self.myDelegate doSomething];  
}
```

IMP (implementation pointer)

IMP is a C type referring to the implementation of a method, also known as an implementation pointer. It is a pointer to the start of a method implementation.

Syntax:

```
id (*IMP)(id, SEL, ...)
```

IMP is defined by:

```
typedef id (*IMP)(id self, SEL _cmd, ...);
```

To access this IMP, the message “**methodForSelector**” can be used.

Example 1:

```
IMP ImpDoSomething = [myObject methodForSelector:@selector(doSomething)];
```

The method addressed by the IMP can be called by dereferencing the IMP.

```
ImpDoSomething(myObject, @selector(doSomething));
```

So these calls are equal:

```

myImpDoSomething(myObject, @selector(doSomething));
[myObject doSomething]
[myObject performSelector:mySelector]
[myObject performSelector:@selector(doSomething)]
[myObject performSelector:NSSelectorFromString(@"doSomething")];

```

Example :2:

```

SEL otherWaySelector = NSSelectorFromString(@"methodWithFirst:andSecond:andThird:");

IMP methodImplementation = [self methodForSelector:otherWaySelector];

result = methodImplementation( self,
                               betterWaySelector,
                               first,
                               second,
                               third );

NSLog(@"methodForSelector : %@", result);

```

Here, we call [NSObject methodForSelector which returns us a pointer to the C function that actually implements the method, which we can the subsequently call directly.

NSInteger and NSUInteger

The NSInteger is just a typedef for either an int or a long depending on the architecture. The same goes for a NSUInteger which is a typedef for the unsigned variants. If you check the NSInteger you will see the following:

```

#if __LP64__ || (TARGET_OS_EMBEDDED && !TARGET_OS_IPHONE) || TARGET_OS_WIN32 ||
NS_BUILD_32_LIKE_64
typedef long NSInteger;
typedef unsigned long NSUInteger;
#else
typedef int NSInteger;
typedef unsigned int NSUInteger;
#endif

```

The difference between an signed and an unsigned int or long is that a signed int or long can contain negative values. The range of the int is -2 147 483 648 to 2 147 483 647 while the unsigned int has a range of 0 to 4 294 967 295. The value is doubled because the first bit isn't used anymore to say the value is negative or not. For a long and NSInteger on 64-bit architectures, the range is much wider.

Most methods Apple provides are returning an NS(U)Integer over the normal int. You'll get a warning if you try to cast it to a normal int because you will lose precision if you are running on a 64-bit architecture. Not that it would matter in most cases, but it is easier to use NS(U)Integer. For example, the count method on a array will return an NSUInteger.

```

NSNumber *iAmNumber = @0;

NSInteger iAmSigned = [iAmNumber integerValue];

```

```
NSInteger iAmUnsigned = [iAmNumber unsignedIntegerValue];

NSLog(@"%ld", iAmSigned); // The way to print a NSInteger.
NSLog(@"%lu", iAmUnsigned); // The way to print a NSUInteger.
```

Just like a BOOL, the NS(U)Integer is a primitive datatype, so you sometimes need to wrap it in a NSNumber you can use the @ before the integer to cast it like above and retrieve it using the methods below. But to cast it to NSNumber, you could also use the following methods:

```
[NSNumber numberWithInt:0];
[NSNumber numberWithUnsignedInteger:0];
```

Read Basic Data Types online: <https://riptutorial.com/objective-c/topic/4564/basic-data-types>

Chapter 3: Blocks

Syntax

- // Declare as a local variable:

```
returnType (^blockName)(parameterType1, parameterType2, ...) = ^returnType(argument1, argument2, ...) {...};
```

- // Declare as a property:

```
@property (nonatomic, copy, nullability) returnType (^blockName)(parameterTypes);
```

- // Declare as a method parameter:

```
- (void)someMethodThatTakesABlock:(returnType (^nullability)(parameterTypes))blockName;
```

- // Declare as an argument to a method call:

```
[someObject someMethodThatTakesABlock:^returnType (parameters) {...}];
```

- // Declare as a typedef:

```
typedef returnType (^TypeName)(parameterTypes);
```

```
TypeName blockName = ^returnType(parameters) {...};
```

- // Declare a C function return a block object:

```
BLOCK_RETURN_TYPE (^function_name(function parameters))(BLOCK_PARAMETER_TYPE);
```

Remarks

Blocks are specified by the [Language Specification for Blocks](#) for C, Objective-C, C++ and Objective-C++.

Additionally, the Blocks ABI is defined by the [Block Implementation Specification](#).

Examples

Blocks as Method Parameters

```
- (void)methodWithBlock:(returnType (^) (paramType1, paramType2, ...))name;
```

Defining and Assigning

A block that performs addition of two double precision numbers, assigned to variable `addition`:

```
double (^addition)(double, double) = ^double(double first, double second){
    return first + second;
};
```

The block can be subsequently called like so:

```
double result = addition(1.0, 2.0); // result == 3.0
```

Blocks as Properties

```
@interface MyObject : MySuperclass

@property (copy) void (^blockProperty)(NSString *string);

@end
```

When assigning, since `self` retains `blockProperty`, block should not contain a strong reference to `self`. Those mutual strong references are called a "retain cycle" and will prevent the release of either object.

```
__weak __typeof(self) weakSelf = self;
self.blockProperty = ^(NSString *string) {
    // refer only to weakSelf here. self will cause a retain cycle
};
```

It is highly unlikely, but `self` might be deallocated inside the block, somewhere during the execution. In this case `weakSelf` becomes `nil` and all messages to it have no desired effect. This might leave the app in an unknown state. This can be avoided by retaining `weakSelf` with a `__strong` ivar during block execution and clean up afterward.

```
__weak __typeof(self) weakSelf = self;
self.blockProperty = ^(NSString *string) {
    __strong __typeof(weakSelf) strongSelf = weakSelf;
    // refer only to strongSelf here.
    // ...
    // At the end of execution, clean up the reference
    strongSelf = nil;
};
```

Block Typedefs

```
typedef double (^Operation)(double first, double second);
```

If you declare a block type as a typedef, you can then use the new type name instead of the full description of the arguments and return values. This defines `Operation` as a block that takes two

doubles and returns a double.

The type can be used for the parameter of a method:

```
- (double)doWithOperation:(Operation)operation
    first:(double)first
    second:(double)second;
```

or as a variable type:

```
Operation addition = ^double(double first, double second){
    return first + second;
};

// Returns 3.0
[self doWithOperation:addition
    first:1.0
    second:2.0];
```

Without the typedef, this is much messier:

```
- (double)doWithOperation:(double (^)(double, double))operation
    first:(double)first
    second:(double)second;

double (^addition)(double, double) = // ...
```

Blocks as local variables

```
returnType (^)(blockName)(parameterType1, parameterType2, ...) = ^returnType(argument1,
argument2, ...) {...};

float (^square)(float) = ^(float x) {return x*x;};

square(5); // resolves to 25
square(-7); // resolves to 49
```

Here's an example with no return and no parameters:

```
NSMutableDictionary *localStatus;
void (^logStatus)() = ^(void){ [MYUniversalLogger logCurrentStatus:localStatus]};

// Insert some code to add useful status information
// to localStatus dictionary

logStatus(); // this will call the block with the current localStatus
```

Read Blocks online: <https://riptutorial.com/objective-c/topic/540/blocks>

Chapter 4: BOOL / bool / Boolean / NSCFBoolean

Examples

BOOL/Boolean/bool/NSCFBoolean

1. bool is a datatype defined in C99.
2. Boolean values are used in conditionals, such as if or while statements, to conditionally perform logic or repeat execution. When evaluating a conditional statement, the value 0 is considered “false”, while any other value is considered “true”. Because NULL and nil are defined as 0, conditional statements on these nonexistent values are also evaluated as “false”.
3. BOOL is an Objective-C type defined as signed char with the macros YES and NO to represent true and false

From the definition in objc.h:

```
#if (TARGET_OS_IPHONE && __LP64__) || TARGET_OS_WATCH
typedef bool BOOL;
#else
typedef signed char BOOL;
// BOOL is explicitly signed so @encode(BOOL) == "c" rather than "C"
// even if -funsigned-char is used.
#endif

#define YES ((BOOL)1)
#define NO  ((BOOL)0)
```

4. NSCFBoolean is a private class in the NSNumber class cluster. It is a bridge to the CFBooleanRef type, which is used to wrap boolean values for Core Foundation property lists and collections. CFBoolean defines the constants kCFBooleanTrue and kCFBooleanFalse. Because CFNumberRef and CFBooleanRef are different types in Core Foundation, it makes sense that they are represented by different bridging classes in NSNumber.

BOOL VS Boolean

BOOL

- Apple's Objective-C frameworks and most Objective-C/Cocoa code uses BOOL.
- Use BOOL in objective-C, when dealing with any CoreFoundation APIs

Boolean

- Boolean is an old Carbon keyword , defined as an unsigned char

Read BOOL / bool / Boolean / NSCFBoolean online: <https://riptutorial.com/objective-c/topic/7267/bool---bool---boolean---nscfboolean>

Chapter 5: Categories

Syntax

- `@interface ClassName (categoryName) // ClassName is the class to be extended`
- `// Method and property declarations`
- `@end`

Remarks

To avoid method name clashes, it is recommended to use prefixes (like `xyz_` in the example). If methods with the same name exist, it is undefined which one will be used in the runtime.

Examples

Simple Category

Interface and implementation of a simple category on NSArray, named Filter, with a single method that filters numbers.

It is good practice to add a prefix (`pf`) to the method to ensure we don't overwrite any future NSArray methods.

```
@interface NSArray (PFFilter)

- (NSArray *)pf_filterSmaller:(double)number;

@end

@implementation NSArray (PFFilter)

- (NSArray *)pf_filterSmaller:(double)number
{
    NSMutableArray *result = [NSMutableArray array];
    for (id val in self)
    {
        if ([val isKindOfClass:[NSNumber class] && [val doubleValue] >= number)
        {
            [result addObject:val];
        }
    }
    return [result copy];
}

@end
```

Declaring a class method

Header file UIColor+XYZPalette.h:

```
@interface UIColor (XYZPalette)

+ (UIColor *)xyz_indigoColor;

@end
```

and implementation UIColor+XYZPalette.m:

```
@implementation UIColor (XYZPalette)

+ (UIColor *)xyz_indigoColor
{
    return [UIColor colorWithRed:75/255.0f green:0/255.0f blue:130/255.0f alpha:1.0f];
}

@end
```

Adding a property with a category

Properties can be added with categories using associated objects, a feature of the Objective-C runtime.

Note that the property declaration of `retain, nonatomic` matches the last argument to `objc_setAssociatedObject`. See [Attach object to another existing object](#) for explanations.

```
#import <objc/runtime.h>

@interface UIViewController (ScreenName)

@property (retain, nonatomic) NSString *screenName;

@end

@implementation UIViewController (ScreenName)

@dynamic screenName;

- (NSString *)screenName {
    return objc_getAssociatedObject(self, @selector(screenName));
}

- (void)setScreenName:(NSString *)screenName {
    objc_setAssociatedObject(self, @selector(screenName), screenName,
    OBJC_ASSOCIATION_RETAIN_NONATOMIC);
}

@end
```

Conforming to protocol

You can add protocols to standard classes to extends their functionality:

```

@protocol EncodableToString <NSObject>
- (NSString *)toString;
@end

@interface NSDictionary (XYZExtended) <EncodableToString>
@end

@implementation NSDictionary (XYZExtended)
- (NSString *)toString {
    return self.description;
}
@end

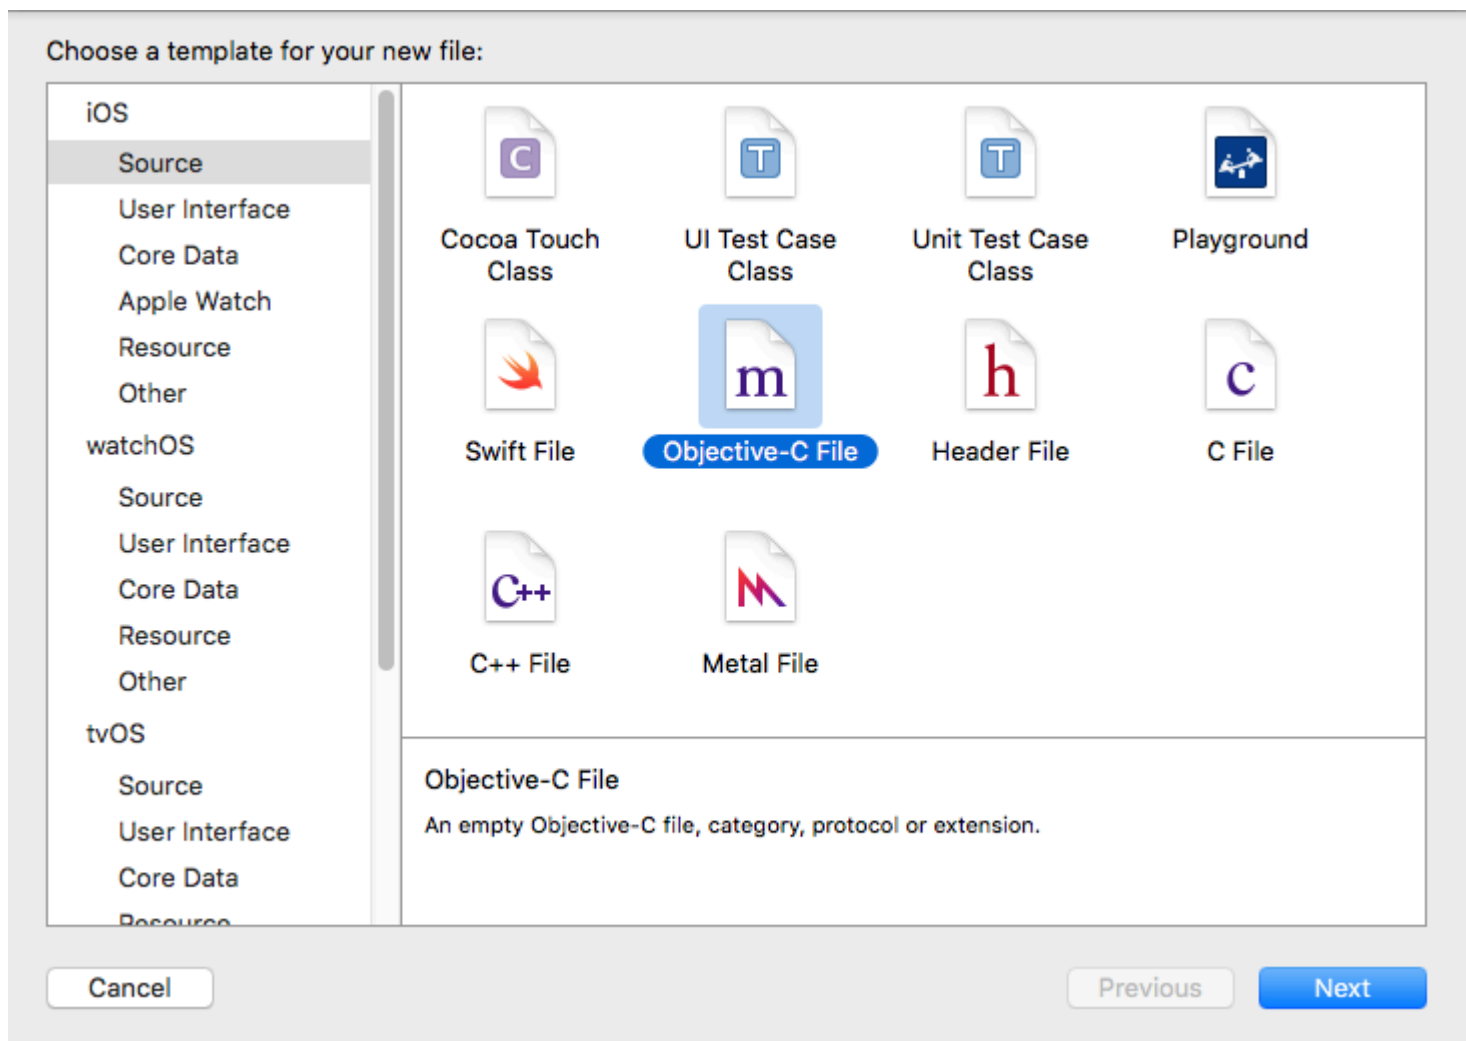

```

where `XYZ` your project's prefix

Create a Category on XCode

Categories provide the ability to add some extra functionality to an object without subclassing or changing the actual object.

For example we want to set some custom fonts. Let's create a category that add functionality to `UIFont` class. Open your XCode project, click on `File -> New -> File` and choose `Objective-C file`, click `Next` enter your category name say `"CustomFont"` choose file type as `Category` and Class as `UIFont` then Click `"Next"` followed by `"Create."`

Choose options for your new file:

File:

File Type:

Class:

Declare the Category Method :-

Click "UIFont+CustomFonts.h" to view the new category's header file. Add the following code to the interface to declare the method.

```
@interface UIFont (CustomFonts)

+ (UIFont *)productSansRegularFontWithSize:(CGFloat)size;

@end
```

Now Implement the Category Method:-

Click "UIFont+CustomFonts.m" to view the category's implementation file. Add the following code to create a method that will set ProductSansRegular Font.

```
+ (UIFont *)productSansRegularFontWithSize:(CGFloat)size{

    return [UIFont fontWithName:@"ProductSans-Regular" size:size];

}
```

Import your category

```
#import "UIFont+CustomFonts.h"
```

Now set the Label font

```
[self.label setFont:[UIFont productSansRegularFontWithSize:16.0]];
```

Read Categories online: <https://riptutorial.com/objective-c/topic/550/categories>

Chapter 6: Classes and Objects

Syntax

- `Cat *cat = [[Cat alloc] init];` // Create cat object of type Cat
- `Dog *dog = [[Dog alloc] init];` // Create dog object of type Dog
- `NSObject *someObject = [NSObject alloc]; [someObject init];` // **don't do this**
- `XYZObject *object = [XYZObject new];` // Use new to create objects if NO arguments are needed for initialization
- `NSString *someString = @"Hello, World!";` // Creating an NSString with *literal syntax*
- `NSNumber *myFloat = @3.14f;` // Another example to create a NSNumber using literal syntax
- `NSNumber *myInt = @(84 / 2);` // Create an object using a boxed expression

Examples

Creating classes with initialization values

```
#import <Foundation/Foundation.h>
@interface Car:NSObject {
    NSString *CarMotorCode;
    NSString *CarChassisCode;
}

- (instancetype)initWithMotorValue:(NSString *) motorCode
andChassisValue:(NSInteger)chassisCode;
- (void) startCar;
- (void) stopCar;

@end

@implementation Car

- (instancetype)initWithMotorValue:(NSString *) motorCode
andChassisValue:(NSInteger)chassisCode{
    CarMotorCode = motorCode;
    CarChassisCode = chassisCode;
    return self;
}

- (void) startCar {...}
- (void) stopCar {...}

@end
```

The method `initWithMotorValue: type andChassisValue: type` will be used to initialize the Car objects.

Singleton Class

What is a Singleton Class?

A singleton class returns the same instance no matter how many times an application requests it. Unlike a regular class, A singleton object provides a global point of access to the resources of its class.

When to Use Singleton Classes?

Singletons are used in situations where this single point of control is desirable, such as with classes that offer some general service or resource.

How to Create Singleton Classes

First, create a New file and subclass it from `NSObject`. Name it anything, we will use `CommonClass` here. Xcode will now generate `CommonClass.h` and `CommonClass.m` files for you.

In your `CommonClass.h` file:

```
#import <Foundation/Foundation.h>

@interface CommonClass : NSObject {
}
+ (CommonClass *)sharedObject;
@property NSString *commonString;
@end
```

In your `CommonClass.m` File:

```
#import "CommonClass.h"

@implementation CommonClass

+ (CommonClass *)sharedObject {
    static CommonClass *sharedClass = nil;
    static dispatch_once_t onceToken;
    dispatch_once(&onceToken, ^{
        sharedClass = [[self alloc] init];
    });
    return sharedClass;
}

- (id)init {
    if (self = [super init]) {
        self.commonString = @"this is string";
    }
    return self;
}

@end
```

How to Use Singleton Classes

The Singleton Class that we created earlier will be accessible from anywhere in the project as long as you have imported `CommonClass.h` file in the relevant module. To modify and access the shared

data in Singleton Class, you will have to access the shared Object of that class which can be accessed by using `sharedObject` method like following:

```
[CommonClass sharedObject]
```

To read or modify the elements in Shared Class, do the following:

```
NSString *commonString = [[CommonClass sharedObject].commonString; //Read the string in
singleton class

NSString *newString = @"New String";
[CommonClass sharedObject].commonString = newString; //Modified the string in singleton class
```

The "instancetype" return type

Objective-C supports a special type called `instancetype` that can only be used as type returned by a method. It evaluates to the class of the receiving object.

Consider the following class hierarchy:

```
@interface Foo : NSObject

- (instancetype)initWithString:(NSString *)string;

@end

@interface Bar : Foo
@end
```

When `[[Foo alloc] initWithString:@"abc"]` is called, the compiler can infer that the return type is `Foo *`. The `Bar` class derived from `Foo` but did not override the declaration of the initializer. Yet, thanks to `instancetype`, the compiler can infer that `[[Bar alloc] initWithString:@"xyz"]` returns a value of type `Bar *`.

Consider the return type of `-[Foo initWithString:]` being `Foo *` instead: if you would call `[[Bar alloc] initWithString:]`, the compiler would infer that a `Foo *` is returned, not a `Bar *` as is the intention of the developer. The `instancetype` solved this issue.

Before the introduction of `instancetype`, initializers, static methods like singleton accessors and other methods that want to return an instance of the receiving class needed to return an `id`. The problem is that `id` means *"an object of any type"*. The compiler is thus not able to detect that `NSString *wrong = [[Foo alloc] initWithString:@"abc"];` is assigning to a variable with an incorrect type.

Due to this issue, **initializers should always use `instancetype` instead of `id`** as the return value.

Specifying Generics

You can enhance your own classes with *generics* just like `NSArray` or `NSDictionary`.

```
@interface MyClass<__covariant T>

@property (nonnull, nonatomic, strong, readonly) NSArray<T>* allObjects;

- (void) addObject:(nonnull T)obj;

@end
```

Difference between allocation and initialization

In most object oriented languages, allocating memory for an object and initializing it is an atomic operation:

```
// Both allocates memory and calls the constructor
MyClass object = new MyClass();
```

In Objective-C, these are separate operations. The class methods `alloc` (and its historic sibling `allocWithZone:`) makes the Objective-C runtime reserve the required memory and clears it. Except for a few internal values, all properties and variables are set to `0/NO/nil`.

The object then is already "valid" but we always want to call a method to actually set up the object, which we call an *initializer*. These serve the same purpose as *constructors* in other languages. By convention, these methods start with `init`. From a language point of view, they are just normal methods.

```
// Allocate memory and set all properties and variables to 0/NO/nil.
MyClass *object = [MyClass alloc];
// Initialize the object.
object = [object init];

// Shorthand:
object = [[MyClass alloc] init];
```

Read Classes and Objects online: <https://riptutorial.com/objective-c/topic/758/classes--and-objects>

Chapter 7: Continue and Break!

Examples

Continue and Break Statement

The continue statement in Objective-C programming language works somewhat like the break statement. Instead of forcing termination, however, continue forces the next iteration of the loop to take place, skipping any code in between.

For the for loop, continue statement causes the conditional test and increment portions of the loop to execute. For the while and do...while loops, continue statement causes the program control pass to the conditional tests.

```
#import <Foundation/Foundation.h>

int main ()
{
    /* local variable definition */
    int a = 10;

    /* do loop execution */
    do
    {
        if( a == 15)
        {
            /* skip the iteration */
            a = a + 1;
            continue;
        }
        NSLog(@"value of a: %d\n", a);
        a++;

    }while( a < 20 );

    return 0;
}
```

Output:

```
2013-09-07 22:20:35.647 demo[29998] value of a: 10
2013-09-07 22:20:35.647 demo[29998] value of a: 11
2013-09-07 22:20:35.647 demo[29998] value of a: 12
2013-09-07 22:20:35.647 demo[29998] value of a: 13
2013-09-07 22:20:35.647 demo[29998] value of a: 14
2013-09-07 22:20:35.647 demo[29998] value of a: 16
2013-09-07 22:20:35.647 demo[29998] value of a: 17
2013-09-07 22:20:35.647 demo[29998] value of a: 18
2013-09-07 22:20:35.647 demo[29998] value of a: 19
```

Refer to this [link](#) for more information.

Read Continue and Break! online: <https://riptutorial.com/objective-c/topic/8709/continue-and-break->

Chapter 8: Declare class method and instance method

Introduction

Instance method are methods that are specific to particular classes. Instance methods are declared and defined followed by - (minus) symbol.

Class methods can be called by class name itself .Class methods are declared and defined by using + (plus)sign .

Syntax

1. -(void)testInstanceMethod; //Class methods declare with "+" sign
2. (void)classMethod;//instance methods declare with "-" sign

Examples

How to declare class method and instance method.

instance methods use an instance of a class.

```
@interface MyTestClass : NSObject  
  
- (void)testInstanceMethod;  
  
@end
```

They could then be used like so:

```
MyTestClass *object = [[MyTestClass alloc] init];  
[object testInstanceMethod];
```

Class method can be used with just the class name.

```
@interface MyClass : NSObject  
  
+ (void)aClassMethod;  
  
@end
```

They could then be used like so:

```
[MyClass aClassMethod];
```

class methods are the convenience methods on many Foundation classes like [NSString's +stringWithFormat:] or NSArray's +arrayWithArray

Read Declare class method and instance method online: <https://riptutorial.com/objective-c/topic/8214/declare-class-method-and-instance-method>

Chapter 9: Enums

Syntax

- `typedef NS_ENUM(type, name) {...}` -- *type* is the type of enumeration and *name* is the name of the enum. values are in "...". This creates a basic enum and a type to go with it; programs like Xcode will assume a variable with the enum type has one of the enum values

Examples

Defining an enum

Enums are defined by the following the syntax above.

```
typedef NS_ENUM(NSUInteger, MyEnum) {  
    MyEnumValueA,  
    MyEnumValueB,  
    MyEnumValueC,  
};
```

You also can set your own raw-values to the enumeration types.

```
typedef NS_ENUM(NSUInteger, MyEnum) {  
    MyEnumValueA = 0,  
    MyEnumValueB = 5,  
    MyEnumValueC = 10,  
};
```

You can also specify on the first value and all the following will use it with increment:

```
typedef NS_ENUM(NSUInteger, MyEnum) {  
    MyEnumValueA = 0,  
    MyEnumValueB,  
    MyEnumValueC,  
};
```

Variables of this enum can be created by `MyEnum enumVar = MyEnumValueA.`

typedef enum declaration in Objective-C

A enum declares a set of ordered values - the typedef just adds a handy name to this. The 1st element is 0 etc.

```
typedef enum {  
    Monday=1,  
    Tuesday,  
    Wednesday
```

```

} WORKDAYS;

WORKDAYS today = Monday;//value 1

```

Converting C++ std::vector to an Objective-C Array

Many C++ libraries use enums and return/receive data using vectors that contain enums. As C enums are not Objective-C objects, Objective-C collections cannot be used directly with C enums. The example below deals with this by using a combination of an NSArray and generics and a wrapper object for the array. This way, the collection can be explicit about the data type and there is no worry about possible memory leaks with C arrays Objective-C objects are used.

Here is the C enum & Objective-C equivalent object:

```

typedef enum
{
    Error0 = 0,
    Error1 = 1,
    Error2 = 2
} MyError;

@interface ErrorEnumObj : NSObject

@property (nonatomic) int intValue;

+ (instancetype) objWithEnum:(MyError) myError;
- (MyError) getEnumValue;

@end

@implementation ErrorEnumObj

+ (instancetype) objWithEnum:(MyError) error
{
    ErrorEnumObj * obj = [ErrorEnumObj new];
    obj.intValue = (int)error;
    return obj;
}

- (MyError) getEnumValue
{
    return (MyError)self.intValue;
}

@end

```

And here is a possible use of it in Objective-C++ (the resulting NSArray can be used in Objective-C only files as no C++ is used).

```

class ListenerImpl : public Listener
{
public:
    ListenerImpl(Listener* listener) : _listener(listener) {}
    void onError(std::vector<MyError> errors) override
    {
        NSMutableArray<ErrorEnumObj *> * array = [NSMutableArray<ErrorEnumObj *> new];
    }
}

```

```
        for (auto&& myError : errors)
        {
            [array addObject:[ErrorEnumObj objWithEnum:myError]];
        }
        [_listener onError:array];
    }

private:
    __weak Listener* _listener;
}
```

If this kind of solution is to be used on multiple enums, the creation of the EnumObj (declaration & implementation) can be done using a macro (to create a template like solution).

Read Enums online: <https://riptutorial.com/objective-c/topic/1461/enums>

Chapter 10: Error Handling

Syntax

- `NSAssert(condition, fmtMessage, arg1, arg2, ...)` (args in italics are optional) -- Asserts that *condition* evaluates to a true value. If it doesn't then the assertion will raise an exception (`NSAssertionException`), with the *fmtMessage* formatted with the args provided

Examples

Asserting

```
@implementation Triangle

...

-(void)setAngles:(NSArray *)_angles {
    self.angles = _angles;

    NSAssert((self.angles.count == 3), @"Triangles must have 3 angles. Array '%@' has %i",
self.angles, (int)self.angles.count);

    CGFloat angleA = [self.angles[0] floatValue];
    CGFloat angleB = [self.angles[1] floatValue];
    CGFloat angleC = [self.angles[2] floatValue];
    CGFloat sum = (angleA + angleB + angleC);
    NSAssert((sum == M_PI), @"Triangles' angles must add up to pi radians (180°). This
triangle's angles add up to %f radians (%f°)", (float)sum, (float)(sum * (180.0f / M_PI)));
}
```

These assertions make sure that you don't give a triangle incorrect angles, by throwing an exception if you do. If they didn't throw an exception than the triangle, not being a true triangle at all, might cause some bugs in later code.

Error & Exception handling with try catch block

Exceptions represent programmer-level bugs like trying to access an array element that doesn't exist.

Errors are user-level issues like trying load a file that doesn't exist. Because errors are expected during the normal execution of a program.

Example:

```
NSArray *inventory = @[@"Sam",
                        @"John",
                        @"Sanju"];

int selectedIndex = 3;

@try {
    NSString * name = inventory[selectedIndex];
}
```

```
    NSLog(@"The selected Name is: %@", name);  
} @catch(NSException *theException) {  
    NSLog(@"An exception occurred: %@", theException.name);  
    NSLog(@"Here are some details: %@", theException.reason);  
} @finally {  
    NSLog(@"Executing finally block");  
}
```

OUTPUT:

An exception occurred: NSRangeException

Here are some details: *** -[__NSArrayI objectAtIndex:]: index 3 beyond bounds [0 .. 2]

Executing finally block

Read Error Handling online: <https://riptutorial.com/objective-c/topic/1459/error-handling>

Chapter 11: Fast Enumeration

Examples

Fast enumeration of an NSArray

This example shows how to use fast enumeration in order to traverse through an NSArray.

When you have an array, such as

```
NSArray *collection = @[@"fast", @"enumeration", @"in objc"];
```

You can use the `for ... in` syntax to go through each item of the array, automatically starting with the first at index 0 and stopping with the last item:

```
for (NSString *item in collection) {  
    NSLog(@"item: %@", item);  
}
```

In this example, the output generated would look like

```
// item: fast  
// item: enumeration  
// item: in objc
```

Fast enumeration of an NSArray with index.

This example shows how to use fast enumeration in order to traverse through an NSArray. With this way you can also track current object's index while traversing.

Suppose you have an array,

```
NSArray *weekDays = @[@"Monday", @"Tuesday", @"Wednesday", @"Thursday", @"Friday",  
@"Saturday", @"Sunday"];
```

Now you can traverse through the array like below,

```
[weekDays enumerateObjectsUsingBlock:^(id obj, NSUInteger idx, BOOL *stop) {  
  
    //... Do your usual stuff here  
  
    obj // This is the current object  
    idx // This is the index of the current object  
    stop // Set this to true if you want to stop  
  
}];
```

Read Fast Enumeration online: <https://riptutorial.com/objective-c/topic/5583/fast-enumeration>

Chapter 12: Format-Specifiers

Introduction

Format-Specifiers are used in Objective-c to implant object-values into a string.

Syntax

- %@ //String
- %d //Signed 32-bit integer
- %D //Signed 32-bit integer
- %u //Unsigned 32-bit integer
- %U //Unsigned 32-bit integer
- %x //Unsigned 32-bit integer in lowercase hexadecimal format
- %X //Unsigned 32-bit integer in UPPERCASE hexadecimal format
- %o //Unsigned 32-bit integer in octal format
- %O //Unsigned 32-bit integer in octal format
- %f //64-bit floating-point number
- %F //64-bit floating-point number printed in decimal notation
- %e //64-bit floating-point number in lowercase scientific notation format
- %E //64-bit floating-point number in UPPERCASE scientific notation format
- %g //special case %e which uses %f when less than 4 sig-figs are available, else %e
- %G //special case %E which uses %f when less than 4 sig-figs are available, else %E
- %c //8-bit unsigned character
- %C //16-bit UTF-16 code unit
- %s //UTF8 String
- %S //16-bit variant of %s
- %p //Void Pointer in lowercase hexadecimal format with leading '0x'
- %zx //special case %p which removes leading '0x' (For use with no-type cast)
- %a //64-bit floating-point number in scientific notation with leading '0x' and one hexadecimal digit before the decimal point using a 'p' to notate the exponent.
- %A //64-bit floating-point number in scientific notation with leading '0x' and one hexadecimal digit before the decimal point using an 'P' to notate the exponent.

Remarks

Due to the nature of format-specifiers, if you wish to include the percentage symbol (%) in your string, you must escape it using a second percentage symbol.

Example:

```
int progress = 45;//percent
NSString *progressString = [NSString stringWithFormat:@"Progress: %i%%", (int)progress];

NSLog(progressString);//logs "Progress: 45%"
```

No Format Specifier for BOOL-type exists.

Common-use solutions include:

```
BOOL myBool = YES;
NSString *boolState = [NSString stringWithFormat:@"BOOL state: %@", myBool?@"true":@"false"];

NSLog(boolState); //logs "true"
```

Which utilizes a ternary operator for casting a string-equivalent.

```
BOOL myBool = YES;
NSString *boolState = [NSString stringWithFormat:@"BOOL state: %i", myBool];

NSLog(boolState); //logs "1" (binary)
```

Which utilizes an (int) cast for implanting a binary-equivalent.

Examples

Integer Example - %i

```
int highScore = 57;
NSString *scoreBoard = [NSString stringWithFormat:@"HighScore: %i", (int)highScore];

NSLog(scoreBoard); //logs "HighScore: 57"
```

Read Format-Specifiers online: <https://riptutorial.com/objective-c/topic/9048/format-specifiers>

Chapter 13: Grand Central Dispatch

Introduction

Grand Central Dispatch (GCD) In iOS, Apple provides two ways to do multitasking: The Grand Central Dispatch (GCD) and NSOperationQueue frameworks. We will discuss here about GCD. GCD is a lightweight way to represent units of work that are going to be executed concurrently. You don't schedule these units of work; the system takes care of scheduling for you. Adding dependency among blocks can be a headache. Canceling or suspending a block creates extra work for you as a developer!

Examples

What is Grand central dispatch.

What is Concurrency?

- Doing multiple things at the same time.
- Taking advantage of number of cores available in multicore CPUs.
- Running multiple programs in parallel.

Objectives of Concurrency

- Running program in background without hogging CPU.
- Define Tasks, Define Rules and let the system take the responsibility of performing them.
- Improve responsiveness by ensuring that the main thread is free to respond to user events.

DISPATCH QUEUES

Grand central dispatch – dispatch queues allows us to execute arbitrary blocks of code either asynchronously or synchronously. All Dispatch Queues are first in – first out. All the tasks added to dispatch queue are started in the order they were added to the dispatch queue.

Read Grand Central Dispatch online: <https://riptutorial.com/objective-c/topic/8280/grand-central-dispatch>

Chapter 14: Inheritance

Syntax

1. @interface derived-class-Name: base-class-Name

Examples

Car is inherited from Vehicle

Consider a base class **Vehicle** and its derived class **Car** as follows:

```
#import <Foundation/Foundation.h>

@interface Vehicle : NSObject

{
    NSString *vehicleName;
    NSInteger vehicleModelNo;
}

- (id)initWithName:(NSString *)name andModel:(NSInteger)modelno;
- (void)print;
@end

@implementation Vehicle

- (id)initWithName:(NSString *)name andModel:(NSInteger)modelno{
    vehicleName = name;
    vehicleModelNo = modelno;
    return self;
}

- (void)print{
    NSLog(@"Name: %@", vehicleName);
    NSLog(@"Model: %ld", vehicleModelNo);
}

@end

@interface Car : Vehicle

{
    NSString *carCompanyName;
}

- (id)initWithName:(NSString *)name andModel:(NSInteger)modelno
andCompanyName:(NSString *)companyname;
- (void)print;

@end

@implementation Car
```

```

- (id)initWithName:(NSString *)name andModel:(NSInteger) modelno
andCompanyName: (NSString *) companyname
{
    vehicleName = name;
    vehicleModelNo = modelno;
    carCompanyName = companyname;
    return self;
}
- (void)print
{
    NSLog(@"Name: %@", vehicleName);
    NSLog(@"Model: %ld", vehicleModelNo);
    NSLog(@"Company: %@", carCompanyName);
}

@end

int main(int argc, const char * argv[])
{
    NSAutoreleasePool * pool = [[NSAutoreleasePool alloc] init];
    NSLog(@"Base class Vehicle Object");
    Vehicle *vehicle = [[Vehicle alloc]initWithName:@"4Wheeler" andModel:1234];
    [vehicle print];
    NSLog(@"Inherited Class Car Object");
    Car *car = [[Car alloc]initWithName:@"S-Class"
andModel:7777 andCompanyName:@"Benz"];
    [car print];
    [pool drain];
    return 0;
}

```

When the above code is compiled and executed, it produces the following result:

2016-09-29 18:21:03.561 Inheritance[349:303] Base class Vehicle Object

2016-09-29 18:21:03.563 Inheritance[349:303] Name: 4Wheeler

Chapter 15: Key Value Coding / Key Value Observing

Examples

Most Common Real Life Key Value Coding Example

Key Value Coding is integrated into **NSObject** using **NSKeyValueCoding** protocol.

What this means?

It means that any id object is capable of calling valueForKey method and its various variants like valueForKeyPath etc. '

It also means that any id object can invoke setValue method and its various variants too.

Example:

```
id obj = [[MyClass alloc] init];
id value = [obj valueForKey:@"myNumber"];

int myNumberAsInt = [value intValue];
myNumberAsInt = 53;
[obj setValue:@(myNumberAsInt) forKey:@"myNumber"];
```

Exceptions:

Above example assumes that MyClass has an NSNumber Property called myNumber. If myNumber does not appear in MyClass interface definition, an NSRangeException can be raised at possibly both lines 2 and 5 - popularly known as:

```
this class is not key value coding-compliant for the key myNumber.
```

Why this is SO powerful:

You can write code that can access properties of a class dynamically, without needing interface for that class. This means that a table view can display values from any properties of an NSObject derived object, provided its property names are supplied dynamically at runtime.

In the example above, the code can as well work without MyClass being available and id type obj being available to calling code.

Key Value Observing

Setting up key value observing.

In this case, we want to observe the `contentOffset` on an object that our observer owns

```

//
// Class to observe
//
@interface XYZScrollView: NSObject
@property (nonatomic, assign) CGPoint contentOffset;
@end

@implementation XYZScrollView
@end

//
// Class that will observe changes
//
@interface XYZObserver: NSObject
@property (nonatomic, strong) XYZScrollView *scrollView;
@end

@implementation XYZObserver

// simple way to create a KVO context
static void *XYZObserverContext = &XYZObserverContext;

// Helper method to add self as an observer to
// the scrollView's contentOffset property
- (void)addObserver {

    // NSKeyValueObservingOptions
    //
    // - NSKeyValueObservingOptionNew
    // - NSKeyValueObservingOptionOld
    // - NSKeyValueObservingOptionInitial
    // - NSKeyValueObservingOptionPrior
    //
    // can be combined:
    // (NSKeyValueObservingOptionNew | NSKeyValueObservingOptionOld)

    NSString *keyPath = NSStringFromSelector(@selector(contentOffset));
    NSKeyValueObservingOptions options = NSKeyValueObservingOptionNew;

    [self.scrollView addObserver: self
                     forKeyPath: keyPath
                     options: options
                     context: XYZObserverContext];
}

- (void)observeValueForKeyPath:(NSString *)keyPath ofObject:(id)object
change:(NSDictionary<NSString *,id> *)change context:(void *)context {

    if (context == XYZObserverContext) { // check the context

        // check the keyPath to see if it's any of the desired keyPath's.
        // You can observe multiple keyPath's
        if ([keyPath isEqualToString: NSStringFromSelector(@selector(contentOffset))]) {

            // change dictionary keys:
            // - NSKeyValueChangeKindKey
            // - NSKeyValueChangeNewKey
            // - NSKeyValueChangeOldKey
            // - NSKeyValueChangeIndexesKey

```

```

        // - NSKeyValueChangeNotificationIsPriorKey

        // the change dictionary here for a CGPoint observation will
        // return an NSPoint, so we can take the CGPointValue of it.
        CGPoint point = [change[NSKeyValueChangeNewKey] CGPointValue];

        // handle point
    }

} else {

    // if the context doesn't match our current object's context
    // we want to pass the observation parameters to super
    [super observeValueForKeyPath: keyPath
                      ofObject: object
                      change: change
                      context: context];

}

}

// The program can crash if an object is not removed as observer
// before it is dealloc'd
//
// Helper method to remove self as an observer of the scrollView's
// contentOffset property
- (void)removeObserver {
    NSString *keyPath = NSStringFromSelector(@selector(contentOffset));
    [self.scrollView removeObserver: self forKeyPath: keyPath];
}

@end

```

Querying KVC Data

```

if ([[dataObject objectForKey:@"yourVariable"] isEqualToString:@"Hello World"]) {
    return YES;
} else {
    return NO;
}

```

You can query values stored using KVC quickly and easily, without needing to retrieve or cast these as local variables.

Collection Operators

Collection Operators can be used in a KVC key path to perform an operation on a “collection-type” property (i.e. `NSArray`, `NSSet` and similar). For example, a common operation to perform is to count the objects in a collection. To achieve this, you use the `@count` *collection operator*.

```

self.array = @[5, 4, 3, 2, 1];
NSNumber *count = [self.array valueForKeyPath:@"@count"];
NSNumber *countAlt = [self valueForKeyPath:@"array.@count"];
// count == countAlt == 5

```

While this is completely redundant here (we could have just accessed the `count` property), it *can*

be useful on occasion, though it is rarely necessary. There are, however, some collection operators that are much more useful, namely `@max`, `@min`, `@sum`, `@avg` and the `@unionOf` family. It is important to note that these operators *also* require a separate key path *following* the operator to function correctly. Here's a list of them and the type of data they work with:

Operator	Data Type
<code>@count</code>	(none)
<code>@max</code>	NSNumber, NSDate, int (and related), etc.
<code>@min</code>	NSNumber, NSDate, int (and related), etc.
<code>@sum</code>	NSNumber, int (and related), double (and related), etc.
<code>@avg</code>	NSNumber, int (and related), double (and related), etc.
<code>@unionOfObjects</code>	NSArray, NSSet, etc.
<code>@distinctUnionOfObjects</code>	NSArray, NSSet, etc.
<code>@unionOfArrays</code>	NSArray<NSArray*>
<code>@distinctUnionOfArrays</code>	NSArray<NSArray*>
<code>@distinctUnionOfSets</code>	NSSet<NSSet*>

`@max` and `@min` will return the highest or lowest value, respectively, of a property of objects in the collection. For example, look at the following code:

```
// "Point" class used in our collection
@interface Point : NSObject

@property NSInteger x, y;

+ (instancetype)pointWithX:(NSInteger)x y:(NSInteger)y;

@end

...

self.points = @[
    [Point pointWithX:0 y:0],
    [Point pointWithX:1 y:-1],
    [Point pointWithX:5 y:-6],
    [Point pointWithX:3 y:0],
    [Point pointWithX:8 y:-4],
];

NSNumber *maxX = [self valueForKeyPath:@"points.@max.x"];
NSNumber *minX = [self valueForKeyPath:@"points.@min.x"];
NSNumber *maxY = [self valueForKeyPath:@"points.@max.y"];
NSNumber *minY = [self valueForKeyPath:@"points.@min.y"];

NSArray<NSNumber*> *boundsOfAllPoints = @[maxX, minX, maxY, minY];
```

...

In just a 4 lines of code and pure Foundation, with the power of Key-Value Coding collection operators we were able to extract a rectangle that encapsulates all of the points in our array.

It is important to note that these comparisons are made by invoking the `compare:` method on the objects, so if you ever want to make your own class compatible with these operators, you must implement this method.

`@sum` will, as you can probably guess, add up all the values of a property.

```
@interface Expense : NSObject

@property NSNumber *price;

+ (instancetype)expenseWithPrice:(NSNumber *)price;

@end

...

self.expenses = @[Expense expenseWithPrice:@1.50],
                 [Expense expenseWithPrice:@9.99],
                 [Expense expenseWithPrice:@2.78],
                 [Expense expenseWithPrice:@9.99],
                 [Expense expenseWithPrice:@24.95]
];

NSNumber *totalExpenses = [self valueForKeyPath:@"expenses.@sum.price"];
```

Here, we used `@sum` to find the total price of all the expenses in the array. If we instead wanted to find the average price we're paying for each expense, we can use `@avg`:

```
NSNumber *averagePrice = [self valueForKeyPath:@"expenses.@avg.price"];
```

Finally, there's the `@unionOf` family. There are five different operators in this family, but they all work mostly the same, with only small differences between each. First, there's `@unionOfObjects` which will return an array of the properties of objects in an array:

```
// See "expenses" array above

NSArray<NSNumber*> *allPrices = [self valueForKeyPath:
    @"expenses.@unionOfObjects.price"];

// Equal to @[ @1.50, @9.99, @2.78, @9.99, @24.95 ]
```

`@distinctUnionOfObjects` functions the same as `@unionOfObjects`, but it removes duplicates:

```
NSArray<NSNumber*> *differentPrices = [self valueForKeyPath:
    @"expenses.@distinctUnionOfObjects.price"];

// Equal to @[ @1.50, @9.99, @2.78, @24.95 ]
```

And finally, the last 3 operators in the `@unionOf` family will go one step deeper and return an array of values found for a property contained inside dually-nested arrays:

```
NSArray<NSArray<Expense*,Expense*>> *arrayOfArrays =
    @[
        @[ [Expense expenseWithPrice:@19.99],
            [Expense expenseWithPrice:@14.95],
            [Expense expenseWithPrice:@4.50],
            [Expense expenseWithPrice:@19.99]
        ],

        @[ [Expense expenseWithPrice:@3.75],
            [Expense expenseWithPrice:@14.95]
        ]
    ];

// @unionOfArrays
NSArray<NSNumber*> allPrices = [arrayOfArrays valueForKeyPath:
    @"@unionOfArrays.price"];
// Equal to @[ @19.99, @14.95, @4.50, @19.99, @3.75, @14.95 ];

// @distinctUnionOfArrays
NSArray<NSNumber*> allPrices = [arrayOfArrays valueForKeyPath:
    @"@distinctUnionOfArrays.price"];
// Equal to @[ @19.99, @14.95, @4.50, @3.75 ];
```

The one missing from this example is `@distinctUnionOfSets`, however this functions exactly the same as `@distinctUnionOfArrays`, but works with and returns `NSSet`s instead (there is no non-distinct version because in a set, every object must be distinct anyway).

And that's it! Collection operators can be really powerful if used correctly, and can help to avoid having to loop through stuff unnecessarily.

One last note: you can also use the standard collection operators on arrays of `NSNumber`s (without additional property access). To do this, you access the `self` pseudo-property that just returns the object:

```
NSArray<NSNumber*> *numbers = @[@0, @1, @5, @27, @1337, @2048];

NSNumber *largest = [numbers valueForKeyPath:@"@max.self"];
NSNumber *smallest = [numbers valueForKeyPath:@"@min.self"];
NSNumber *total = [numbers valueForKeyPath:@"@sum.self"];
NSNumber *average = [numbers valueForKeyPath:@"@avg.self"];
```

Chapter 16: Logging

Syntax

- `NSLog(@"text to log");` // Basic text log
- `NSLog(@"data: %f - %.2f", myFloat, anotherFloat);` // Logging text including float numbers.
- `NSLog(@"data: %i", myInteger);` // Logging text including integer number.
- `NSLog(@"data: %@", myStringOrObject);` // Logging text referencing another String or any NSObject derived object.

Remarks

For logging various types of objects and data-types refer to: [Objective-C, Format Specifiers](#)

Examples

Logging

```
NSLog(@"Log Message!");
NSLog(@"NSString value: %@", stringValue);
NSLog(@"Integer value: %d", intValue);
```

The first argument of `NSLog` is an `NSString` containing the log message format. The rest of the parameters are used as values to substitute in place of the format specifiers.

The formatting works exactly the same as `printf`, except for the additional format specifier `%@` for an arbitrary Objective-C object. This:

```
NSLog(@"%@", object);
```

is equivalent to:

```
NSLog(@"%s", [object description].UTF8String);
```

NSLog vs printf

```
NSLog(@"NSLog message");
printf("printf message\n");
```

Output:

```
2016-07-16 08:58:04.681 test[46259:1244773] NSLog message
printf message
```

NSLog

outputs the date, time, process name, process ID, and thread ID in addition to the log message. `printf` just outputs the message.

`NSLog` requires an `NSString` and automatically adds a newline at the end. `printf` requires a C string and does not automatically add a newline.

`NSLog` sends output to `stderr`, `printf` sends output to `stdout`.

Some format-specifiers in `printf` vs `NSLog` are different. For example when including a nested string, the following differences incur:

```
NSLog(@"My string: %@", (NSString *)myString);
printf("My string: %s", [(NSString *)myString UTF8String]);
```

NSLog Output Format

```
NSLog(@"NSLog message");
```

The message that gets printed by calling `NSLog` has the following format when viewed in Console.app:

Date	Time	Program name	Process ID		Thread ID	Message
2016-07-16	08:58:04.681	test	[46259	:	1244773]	NSLog message

Logging Variable Values

You shouldn't call `NSLog` without a literal format string like this:

```
NSLog(variable); // Dangerous code!
```

If the variable is not an `NSString`, the program will crash, because `NSLog` expects an `NSString`.

If the variable is an `NSString`, it will work unless your string contains a `%`. `NSLog` will parse the `%` sequence as a format specifier and then read a garbage value off the stack, causing a crash or even [executing arbitrary code](#).

Instead, always make the first argument a format specifier, like this:

```
NSLog(@"%@", anObjectVariable);
NSLog(@"%d", anIntegerVariable);
```

Empty message is not printed

When `NSLog` is asked to print empty string, it omits the log completely.

```
NSString *name = @"";
NSLog(@"%@", name); // Resolves to @""
```

The above code will print **nothing**.

It is a good practice to prefix logs with labels:

```
NSString *name = @"";
NSLog(@"Name: %@", name); // Resolves to @"Name: "
```

The above code will print:

```
2016-07-21 14:20:28.623 App[87711:6153103] Name:
```

Removing Log Statements from Release Builds

Messages printed from `NSLog` are displayed on Console.app even in the release build of your app, which doesn't make sense for printouts that are only useful for debugging. To fix this, you can use this macro for debug logging instead of `NSLog`.

```
#ifdef DEBUG
#define DLog(...) NSLog(__VA_ARGS__)
#else
#define DLog(...)
#endif
```

To use:

```
NSString *value = @"value 1";
DLog(@"value = %@", value);
// little known fact: programmers look for job postings in Console.app
NSLog(@"We're hiring!");
```

In debug builds, `DLog` will call `NSLog`. In release builds, `DLog` will do nothing.

Using `__FUNCTION__`

```
NSLog(@"%s %@", __FUNCTION__, @"etc etc");
```

Inserts the class and method name into the output:

```
2016-07-22 12:51:30.099 loggingExample[18132:2971471] -[ViewController viewDidLoad] etc etc
```

NSLog and BOOL type

There is no format specifier to print boolean type using `NSLog`. One way to print boolean value is to convert it to a string.

```
BOOL boolValue = YES;
NSLog(@"Bool value %@", boolValue ? @"YES" : @"NO");
```

Output:

```
2016-07-30 22:53:18.269 Test[4445:64129] Bool value YES
```

Another way to print boolean value is to cast it to integer, achieving a binary output (1=yes, 0=no).

```
BOOL boolValue = YES;
NSLog(@"Bool value %i", boolValue);
```

Output:

```
2016-07-30 22:53:18.269 Test[4445:64129] Bool value 1
```

Logging NSLog meta data

```
NSLog(@"%s %d %s, yourVariable: %@", __FILE__, __LINE__, __PRETTY_FUNCTION__, yourVariable);
```

Will log the file, line number and function data along with any variables you want to log. This can make the log lines much longer, particularly with verbose file and method names, however it can help to speed up error diagnostics.

You can also wrap this in a Macro (store this in a Singleton or where you'll need it most);

```
#define ALog(fmt, ...) NSLog((@"%s [Line %d] " fmt), __PRETTY_FUNCTION__, __LINE__,  
##__VA_ARGS__);
```

Then when you want to log, simply call

```
ALog(@"name: %@", firstName);
```

Which will give you something like;

```
-[AppDelegate application:didFinishLaunchingWithOptions:] [Line 27] name: John
```

Logging by Appending to a File

NSLog is good, but you can also log by appending to a file instead, using code like:

```
NSFileHandle* fh = [NSFileHandle fileHandleForWritingAtPath:path];  
if ( !fh ) {  
    [[NSFileManager defaultManager] createFileAtPath:path contents:nil attributes:nil];  
    fh = [NSFileHandle fileHandleForWritingAtPath:path];  
}  
if ( fh ) {
```

```
@try {  
    [fh seekToEndOfFile];  
    [fh writeData:[self dataUsingEncoding:enc]];  
}  
@catch (...) {  
}  
[fh closeFile];  
}
```

Read Logging online: <https://riptutorial.com/objective-c/topic/724/logging>

Chapter 17: Low-level Runtime Environment

Remarks

In order to use the Objective-C runtime, you need to import it.

```
#import <objc/objc.h>
```

Examples

Attach object to another existing object (association)

It's possible to attach an object to an existing object as if there was a new property. This is called *association* and allows one to extend existing objects. It can be used to provide storage when adding a property via a class extension or otherwise add additional information to an existing object.

The associated object is automatically released by the runtime once the target object is deallocated.

```
#import <objc/runtime.h>

// "Key" for association. Its value is never used and doesn't
// matter. The only purpose of this global static variable is to
// provide a guaranteed unique value at runtime: no two distinct
// global variables can share the same address.
static char key;

id target = ...;
id payload = ...;
objc_setAssociateObject(target, &key, payload, OBJC_ASSOCIATION_RETAIN);
// Other useful values are OBJC_ASSOCIATION_COPY
// and OBJ_ASSOCIATION_ASSIGN

id queryPayload = objc_getAssociatedObject(target, &key);
```

Augmenting methods using Method Swizzling

The Objective-C runtime allows you to change the implementation of a method at runtime. This is called *method swizzling* and is often used to exchange the implementations of two methods. For example, if the methods `foo` and `bar` are exchanged, sending the message `foo` will now execute the implementation of `bar` and vice versa.

This technique can be used to augment or "patch" existing methods which you cannot edit directly, such as methods of system-provided classes.

In the following example, the `-[NSUserDefaults synchronize]` method is augmented to print the execution time of the original implementation.

IMPORTANT: Many people try to do swizzling using `method_exchangeImplementations`. However, this approach is dangerous if you need to call the method you're replacing, because you'll be calling it using a different selector than it is expecting to receive. As a result, your code can break in strange and unexpected ways—particularly if multiple parties swizzle an object in this way. Instead, you should always do swizzling using `setImplementation` in conjunction with a C function, allowing you to call the method with the original selector.

```
#import "NSUserDefaults+Timing.h"
#import <objc/runtime.h> // Needed for method swizzling

static IMP old_synchronize = NULL;

static void new_synchronize(id self, SEL _cmd);

@implementation NSUserDefaults(Timing)

+ (void)load
{
    Method originalMethod = class_getInstanceMethod([self class], @selector(synchronize:));
    IMP swizzleImp = (IMP)new_synchronize;
    old_synchronize = method_setImplementation(originalMethod, swizzleImp);
}
@end

static void new_synchronize(id self, SEL _cmd);
{
    NSDate *started;
    BOOL returnValue;

    started = [NSDate date];

    // Call the original implementation, passing the same parameters
    // that this function was called with, including the selector.
    returnValue = old_synchronize(self, _cmd);

    NSLog(@"Writing user defaults took %f seconds.", [[NSDate date]
timeIntervalSinceDate:started]);

    return returnValue;
}

@end
```

If you need to swizzle a method that takes parameters, you just add them as additional parameters to the function. For example:

```
static IMP old_viewWillAppear_animated = NULL;
static void new_viewWillAppear_animated(id self, SEL _cmd, BOOL animated);

...

Method originalMethod = class_getClassMethod([UIViewController class],
@selector(viewWillAppear:));
IMP swizzleImp = (IMP)new_viewWillAppear_animated;
old_viewWillAppear_animated = method_setImplementation(originalMethod, swizzleImp);
```

```

...

static void new_viewWillAppear_animated(id self, SEL _cmd, BOOL animated)
{
    ...

    old_viewWillAppear_animated(self, _cmd, animated);

    ...
}

```

Calling methods directly

If you need to call an Objective-C method from C code, you have two ways: using `objc_msgSend`, or obtaining the `IMP` (method implementation function pointer) and calling that.

```

#import <objc/objc.h>

@implementation Example

- (double)negate:(double)value {
    return -value;
}

- (double)invert:(double)value {
    return 1 / value;
}

@end

// Calls the selector on the object. Expects the method to have one double argument and return
// a double.
double performSelectorWithMsgSend(id object, SEL selector, double value) {
    // We declare pointer to function and cast `objc_msgSend` to expected signature.
    // WARNING: This step is important! Otherwise you may get unexpected results!
    double (*msgSend)(id, SEL, double) = (typeof(msgSend)) &objc_msgSend;

    // The implicit arguments of self and _cmd need to be passed in addition to any explicit
    // arguments.
    return msgSend(object, selector, value);
}

// Does the same as the above function, but by obtaining the method's IMP.
double performSelectorWithIMP(id object, SEL selector, double value) {
    // Get the method's implementation.
    IMP imp = class_getMethodImplementation([self class], selector);

    // Cast it so the types are known and ARC can work correctly.
    double (*callableImp)(id, SEL, double) = (typeof(callableImp)) imp;

    // Again, you need the explicit arguments.
    return callableImp(object, selector, value);
}

int main() {
    Example *e = [Example new];

    // Invoke negation, result is -4
    double x = performSelectorWithMsgSend(e, @selector(negate:), 4);
}

```

```
// Invoke inversion, result is 0.25
double y = performSelectorWithIMP(e, @selector(invert:), 4);
}
```

`objc_msgSend` works by obtaining the IMP for the method and calling that. The IMPs for the last several methods called are cached, so if you're sending an Objective-C message in a very tight loop you can get acceptable performance. In some cases, manually caching the IMP can give slightly better performance, although this is a last resort optimization.

Read Low-level Runtime Environment online: <https://riptutorial.com/objective-c/topic/1180/low-level-runtime-environment>

Chapter 18: Memory Management

Examples

Automatic Reference Counting

With automatic reference counting (ARC), the compiler inserts `retain`, `release`, and `autorelease` statements where they are needed, so you don't have to write them yourself. It also writes `dealloc` methods for you.

The sample program from Manual Memory Management looks like this with ARC:

```
@interface MyObject : NSObject {
    NSString *_property;
}
@end

@implementation MyObject
@synthesize property = _property;

- (id)initWithProperty:(NSString *)property {
    if (self = [super init]) {
        _property = property;
    }
    return self;
}

- (NSString *)property {
    return property;
}

- (void)setProperty:(NSString *)property {
    _property = property;
}
@end
```

```
int main() {
    MyObject *obj = [[MyObject alloc] init];

    NSString *value = [[NSString alloc] initWithString:@"value"];
    [obj setProperty:value];

    [obj setProperty:@"value"];
}
```

You are still able to override the `dealloc` method to clean up resources not handled by ARC. Unlike when using manual memory management you do not call `[super dealloc]`.

```
-(void)dealloc {
    //clean up
}
```

Strong and weak references

Modern

A weak reference looks like one of these:

```
@property (weak) NSString *property;  
NSString *__weak variable;
```

If you have a weak reference to an object, then under the hood:

- You're not retaining it.
- When it gets deallocated, every reference to it will automatically be set to `nil`

Object references are always strong by default. But you can explicitly specify that they're strong:

```
@property (strong) NSString *property;  
NSString *__strong variable;
```

A strong reference means that while that reference exists, you are retaining the object.

Manual Memory Management

This is an example of a program written with manual memory management. You really shouldn't write your code like this, unless for some reason you can't use ARC (like if you need to support 32-bit). The example avoids `@property` notation to illustrate how you used to have to write getters and setters.

```
@interface MyObject : NSObject {  
    NSString *_property;  
}  
@end  
  
@implementation MyObject  
@synthesize property = _property;  
  
- (id)initWithProperty:(NSString *)property {  
    if (self = [super init]) {  
        // Grab a reference to property to make sure it doesn't go away.  
        // The reference is released in dealloc.  
        _property = [property retain];  
    }  
    return self;  
}  
  
- (NSString *)property {  
    return [[property retain] autorelease];  
}  
  
- (void)setProperty:(NSString *)property {  
    // Retain, then release. So setting it to the same value won't lose the reference.  
    [property retain];  
    [_property release];  
    _property = property;  
}
```

```

}

- (void)dealloc {
    [_property release];
    [super dealloc]; // Don't forget!
}

@end

```

```

int main() {
    // create object
    // obj is a reference that we need to release
    MyObject *obj = [[MyObject alloc] init];

    // We have to release value because we created it.
    NSString *value = [[NSString alloc] initWithString:@"value"];
    [obj setProperty:value];
    [value release];

    // However, string constants never need to be released.
    [obj setProperty:@"value"];
    [obj release];
}

```

Memory management rules when using manual reference counting.

These rules apply only if you use manual reference counting!

1. You own any object you create

By calling a method whose name begins with `alloc`, `new`, `copy` or `mutableCopy`. For example:

```

NSObject *object1 = [[NSObject alloc] init];
NSObject *object2 = [NSObject new];
NSObject *object3 = [object2 copy];

```

That means that you are responsible for releasing these objects when you are done with them.

2. You can take ownership of an object using retain

To take ownership for an object you call the `retain` method.

For example:

```

NSObject *object = [NSObject new]; // object already has a retain count of 1
[object retain]; // retain count is now 2

```

This makes only sense in some rare situations.

For example when you implement an accessor or an `init` method to take ownership:

```

- (void)setStringValue:(NSString *)stringValue {

```

```
[_privateStringValue release]; // Release the old value, you no longer need it
[stringValue retain]; // You make sure that this object does not get deallocated
outside of your scope.
_privateStringValue = stringValue;
}
```

3. When you no longer need it, you must relinquish ownership of an object you own

```
NSObject* object = [NSObject new]; // The retain count is now 1
[object performAction1]; // Now we are done with the object
[object release]; // Release the object
```

4. You must not relinquish ownership of an object you do not own

That means when you didn't take ownership of an object you don't release it.

5. Autoreleasepool

The autoreleasepool is a block of code that releases every object in the block that received an autorelease message.

Example:

```
@autoreleasepool {
    NSString* string = [NSString stringWithString:@"We don't own this object"];
}
```

We have created a string without taking ownership. The `NSString` method `stringWithString:` has to make sure that the string is correctly deallocated after it is no longer needed. Before the method returns the newly created string calls the autorelease method so it does not have to take ownership of the string.

This is how the `stringWithString:` is implemented:

```
+ (NSString *)stringWithString:(NSString *)string {
    NSString *createdString = [[NSString alloc] initWithString:string];
    [createdString autorelease];
    return createdString;
}
```

It is necessary to use autoreleasepool blocks because you sometimes have objects that you don't own (the fourth rule does not always apply).

Automatic reference counting takes automatically care of the rules so you don't have to.

Read Memory Management online: <https://riptutorial.com/objective-c/topic/2751/memory-management>

Chapter 19: Methods

Syntax

- - or +: The type of method. Instance or class?
- (): Where the return type goes. Use void if you don't want to return anything!
- Next is the name of the method. Use camelCase and make the name easy to remember and understand.
- If your method needs parameters, now is the time! The first parameter comes right after the name of the function like this : (type)parameterName. All the other parameters are done this way parameterLabel: (type)parameterName
- What does your method do? Put it all here, in the curly braces {}!

Examples

Method parameters

If you want to pass in values to a method when it is called, you use parameters:

```
- (int)addInt:(int)intOne toInt:(int)intTwo {  
    return intOne + intTwo;  
}
```

The colon (:) separates the parameter from the method name.

The parameter type goes in the parentheses (int).

The parameter name goes after the parameter type.

Create a basic method

This is how to create a basic method that logs 'Hello World' to the console:

```
- (void)hello {  
    NSLog(@"Hello World");  
}
```

The - at the beginning denotes this method as an instance method.

The (void) denotes the return type. This method doesn't return anything, so you enter void.

The 'hello' is the name of the method.

Everything in the {} is the code run when the method is called.

Return values

When you want to return a value from a method, you put the type you want to return in the first set of parentheses.

```
- (NSString)returnHello {  
    return @"Hello World";  
}
```

The value you want to return goes after the `return` keyword;

Class methods

A class method is called on the class the method belongs to, not an instance of it. This is possible because Objective-C classes are also objects. To denote a method as a class method, change the - to a +:

```
+ (void)hello {  
    NSLog(@"Hello World");  
}
```

Calling methods

Calling an instance method:

```
[classInstance hello];  
  
@interface Sample  
-(void)hello; // exposing the class Instance method  
@end  
  
@implementation Sample  
-(void)hello{  
    NSLog(@"hello");  
}  
@end
```

Calling an instance method on the current instance:

```
[self hello];  
  
@implementation Sample  
  
-(void)otherMethod{  
    [self hello];  
}  
  
-(void)hello{  
    NSLog(@"hello");  
}
```

```
@end
```

Calling a method that takes arguments:

```
[classInstance addInt:1 toInt:2];

@implementation Sample
- (void)add: (NSInteger)add to: (NSInteger)to
    NSLog(@"sum = %d", (add+to));
}
@end
```

Calling a class method:

```
[Class hello];

@interface Sample
+ (void)hello; // exposing the class method
@end

@implementation Sample
+ (void)hello{
    NSLog(@"hello");
}
@end
```

Instance methods

An instance method is a method that's available on a particular instance of a class, after the instance has been instantiated:

```
MyClass *instance = [MyClass new];
[instance someInstanceMethod];
```

Here's how you define one:

```
@interface MyClass : NSObject

- (void)someInstanceMethod; // "-" denotes an instance method

@end

@implementation MyClass

- (void)someInstanceMethod {
    NSLog(@"Whose idea was it to have a method called \"%someInstanceMethod\"?");
}

@end
```

Pass by value parameter passing

In pass by value of parameter passing to a method, actual parameter value is copied to formal

parameter value. So actual parameter value will not change after returning from called function.

```
@interface SwapClass : NSObject

-(void) swap:(NSInteger)num1 andNum2:(NSInteger)num2;

@end

@implementation SwapClass

-(void) num:(NSInteger)num1 andNum2:(NSInteger)num2{
    int temp;
    temp = num1;
    num1 = num2;
    num2 = temp;
}

@end
```

Calling the methods:

```
NSInteger a = 10, b =20;
SwapClass *swap = [[SwapClass alloc]init];
NSLog(@"Before calling swap: a=%d,b=%d",a,b);
[swap num:a andNum2:b];
NSLog(@"After calling swap: a=%d,b=%d",a,b);
```

Output:

```
2016-07-30 23:55:41.870 Test[5214:81162] Before calling swap: a=10,b=20
2016-07-30 23:55:41.871 Test[5214:81162] After calling swap: a=10,b=20
```

Pass by reference parameter passing

In pass by reference of parameter passing to a method, address of actual parameter is passed to formal parameter. So actual parameter value will be changed after returning from called function.

```
@interface SwapClass : NSObject

-(void) swap:(int*)num1 andNum2:(int*)num2;

@end

@implementation SwapClass

-(void) num:(int*)num1 andNum2:(int*)num2{
    int temp;
    temp = *num1;
    *num1 = *num2;
    *num2 = temp;
}

@end
```

Calling the methods:

```
int a = 10, b =20;
SwapClass *swap = [[SwapClass alloc]init];
NSLog(@"Before calling swap: a=%d,b=%d",a,b);
[swap num:&a andNum2:&b];
NSLog(@"After calling swap: a=%d,b=%d",a,b);
```

Output:

```
2016-07-31 00:01:47.067 Test[5260:83491] Before calling swap: a=10,b=20
2016-07-31 00:01:47.070 Test[5260:83491] After calling swap: a=20,b=10
```

Read Methods online: <https://riptutorial.com/objective-c/topic/1457/methods>

Chapter 20: Modern Objective-C

Examples

Literals

Modern Objective C provides ways to reduce amount of code you need to initialize some common types. This new way is very similar to how NSString objects are initialized with constant strings.

NSNumber

Old way:

```
NSNumber *number = [NSNumber numberWithInt:25];
```

Modern way:

```
NSNumber *number = @25;
```

Note: you can also store `BOOL` values in `NSNumber` objects using `@YES`, `@NO` or `@(someBoolValue)`;

NSArray

Old way:

```
NSArray *array = [[NSArray alloc] initWithObjects:@"One", @"Two", [NSNumber numberWithInt:3],  
@"Four", nil];
```

Modern way:

```
NSArray *array = @[@"One", @"Two", @3, @"Four"];
```

NSDictionary

Old way:

```
NSDictionary *dictionary = [NSDictionary dictionaryWithObjectsAndKeys: array, @"Object",  
[NSNumber numberWithFloat:1.5], @"Value", @"ObjectiveC", @"Language", nil];
```

Modern way:

```
NSDictionary *dictionary = @{@"Object": array, @"Value": @1.5, @"Language": @"ObjectiveC"};
```

Container subscripting

In modern Objective C syntax you can get values from `NSArray` and `NSDictionary` containers using container subscripting.

Old way:

```
NSObject *object1 = [array objectAtIndex:1];
NSObject *object2 = [dictionary objectForKey:@"Value"];
```

Modern way:

```
NSObject *object1 = array[1];
NSObject *object2 = dictionary[@"Value"];
```

You can also insert objects into arrays and set objects for keys in dictionaries in a cleaner way:

Old way:

```
// replacing at specific index
[mutableArray replaceObjectAtIndex:1 withObject:@"NewValue"];
// adding a new value to the end
[mutableArray addObject:@"NewValue"];

[mutableDictionary setObject:@"NewValue" forKey:@"NewKey"];
```

Modern way:

```
mutableArray[1] = @"NewValue";
mutableArray[mutableArray count] = @"NewValue";

mutableDictionary[@"NewKey"] = @"NewValue";
```

Read Modern Objective-C online: <https://riptutorial.com/objective-c/topic/9486/modern-objective-c>

Chapter 21: Multi-Threading

Examples

Creating a simple thread

The most simple way to create a thread is by calling a selector "in the background". This means a new thread is created to execute the selector. The receiving object can be any object, not just `self`, but it needs to respond to the given selector.

```
- (void)createThread {
    [self performSelectorInBackground:@selector(threadMainWithOptionalArgument:)
        withObject:someObject];
}

- (void)threadMainWithOptionalArgument:(id)argument {
    // To avoid memory leaks, the first thing a thread method needs to do is
    // create a new autorelease pool, either manually or via "@autoreleasepool".
    @autoreleasepool {
        // The thread code should be here.
    }
}
```

Create more complex thread

Using a subclass of `NSThread` allows implementation of more complex threads (for example, to allow passing more arguments or to encapsulate all related helper methods in one class). Additionally, the `NSThread` instance can be saved in a property or variable and can be queried about its current state (whether it's still running).

The `NSThread` class supports a method called `cancel` that can be called from any thread, which then sets the `cancelled` property to `YES` in a thread-safe way. The thread implementation can query (and/or observe) the `cancelled` property and exit its `main` method. This can be used to gracefully shut down a worker thread.

```
// Create a new NSThread subclass
@interface MyThread : NSThread

// Add properties for values that need to be passed from the caller to the new
// thread. Caller must not modify these once the thread is started to avoid
// threading issues (or the properties must be made thread-safe using locks).
@property NSInteger someProperty;

@end

@implementation MyThread

- (void)main
{
    @autoreleasepool {
        // The main thread method goes here
    }
}
```

```
        NSLog(@"New thread. Some property: %ld", (long)self.someProperty);
    }
}

@end

MyThread *thread = [[MyThread alloc] init];
thread.someProperty = 42;
[thread start];
```

Thread-local storage

Every thread has access to a mutable dictionary that is local to the current thread. This allows to cache informations in an easy way without the need for locking, as each thread has its own dedicated mutable dictionary:

```
NSMutableDictionary *localStorage = [NSThread currentThread].threadDictionary;
localStorage[someKey] = someValue;
```

The dictionary is automatically released when the thread terminates.

Read Multi-Threading online: <https://riptutorial.com/objective-c/topic/3350/multi-threading>

Chapter 22: NSArray

Syntax

- `NSArray *words; // Declaring immutable array`
- `NSMutableArray *words; // Declaring mutable array`
- `NSArray *words = [NSArray arrayWithObjects: @"one", @"two", nil]; // Array initialization syntax`
- `NSArray *words = @[@"list", @"of", @"words", @123, @3.14]; // Declaring array literals`
- `NSArray *stringArray = [NSArray arrayWithObjects: [NSMutableArray array], [NSMutableArray array], nil]; // Creating multidimensional arrays`

Examples

Creating Arrays

Creating immutable arrays:

```
NSArray *myColors = [NSArray arrayWithObjects: @"Red", @"Green", @"Blue", @"Yellow", nil];

// Using the array literal syntax:
NSArray *myColors = @[@"Red", @"Green", @"Blue", @"Yellow"];
```

For mutable arrays, see [NSMutableArray](#).

Finding out the Number of Elements in an Array

```
NSArray *myColors = [NSArray arrayWithObjects: @"Red", @"Green", @"Blue", @"Yellow", nil];
NSLog(@"Number of elements in array = %lu", [myColors count]);
```

Accessing elements

```
NSArray *myColors = @[@"Red", @"Green", @"Blue", @"Yellow"];
// Preceding is the preferred equivalent to [NSArray arrayWithObjects:...]
```

Getting a single item

The `objectAtIndex:` method provides a single object. The first object in an `NSArray` is index 0. Since an `NSArray` can be homogenous (holding different types of objects), the return type is `id` ("any object"). (An `id` can be assigned to a variable of any other object type.) Importantly, `NSArray`s can only contain objects. They cannot contain values like `int`.

```
NSUInteger idx = 2;
NSString *color = [myColors objectAtIndex:idx];
// color now points to the string @"Green"
```

Clang provides a better subscript syntax [as part of its array literals functionality](#):

```
NSString *color = myColors[idx];
```

Both of these throw an exception if the passed index is less than 0 or greater than `count - 1`.

First and Last Item

```
NSString *firstColor = myColors.firstObject;  
NSString *lastColor = myColors.lastObject;
```

The `firstObject` and `lastObject` are computed properties and return `nil` rather than crashing for empty arrays. For single element arrays they return the same object. Although, the `firstObject` method was not introduced to `NSArray` until iOS 4.0.

```
NSArray *empty = @[]  
id notAnObject = empty.firstObject;    // Returns `nil`  
id kaboom = empty[0];                 // Crashes; index out of bounds
```

Filtering Arrays With Predicates

```
NSArray *array = [NSArray arrayWithObjects:@"Nick", @"Ben", @"Adam", @"Melissa", nil];  
  
NSPredicate *aPredicate = [NSPredicate predicateWithFormat:@"SELF beginswith[c] 'a']";  
NSArray *beginWithA = [array filteredArrayUsingPredicate:aPredicate];  
    // beginWithA contains { @"Adam" }.  
  
NSPredicate *ePredicate = [NSPredicate predicateWithFormat:@"SELF contains[c] 'e']";  
[array filterUsingPredicate:ePredicate];  
    // array now contains { @"Ben", @"Melissa" }
```

More about

[NSPredicate](#):

Apple doc : [NSPredicate](#)

Converting NSArray to NSMutableArray to allow modification

```
NSArray *myColors = [NSArray arrayWithObjects:@"Red", @"Green", @"Blue", @"Yellow", nil];  
  
// Convert myColors to mutable  
NSMutableArray *myColorsMutable = [myColors mutableCopy];
```

Sorting array with custom objects

Compare method

Either you implement a compare-method for your object:

```
- (NSComparisonResult)compare:(Person *)otherObject {
    return [self.birthDate compare:otherObject.birthDate];
}

NSArray *sortedArray = [drinkDetails sortedArrayUsingSelector:@selector(compare:)];
```

NSSortDescriptor

```
NSSortDescriptor *sortDescriptor;
sortDescriptor = [[NSSortDescriptor alloc] initWithKey:@"birthDate"
                                                    ascending:YES];
NSArray *sortDescriptors = [NSArray arrayWithObject:sortDescriptor];
NSArray *sortedArray = [drinkDetails sortedArrayUsingDescriptors:sortDescriptors];
```

You can easily sort by multiple keys by adding more than one to the array. Using custom comparator-methods is possible as well. Have a look at [the documentation](#).

Blocks

```
NSArray *sortedArray;
sortedArray = [drinkDetails sortedArrayUsingComparator:^(NSComparisonResult(id a, id b) {
    NSDate *first = [(Person*)a birthDate];
    NSDate *second = [(Person*)b birthDate];
    return [first compare:second];
})];
```

Performance

The `-compare:` and block-based methods will be quite a bit faster, in general, than using `NSSortDescriptor` as the latter relies on KVC. The primary advantage of the `NSSortDescriptor` method is that it provides a way to define your sort order using data, rather than code, which makes it easy to e.g. set things up so users can sort an `NSTableView` by clicking on the header row.

Converting between Sets and Arrays

```
NSSet *set = [NSSet set];
NSArray *array = [NSArray array];

NSArray *fromSet = [set allObjects];
NSSet *fromArray = [NSSet setWithArray:array];
```

Reverse an Array

```
NSArray *reversedArray = [myArray.reverseObjectEnumerator allObjects];
```

Looping through

```
NSArray *myColors = @[@"Red", @"Green", @"Blue", @"Yellow"];

// Fast enumeration
// myColors cannot be modified inside the loop
for (NSString *color in myColors) {
    NSLog(@"Element %@", color);
}

// Using indices
for (NSUInteger i = 0; i < myColors.count; i++) {
    NSLog(@"Element %d = %@", i, myColors[i]);
}

// Using block enumeration
[myColors enumerateObjectsUsingBlock:^(id obj, NSUInteger idx, BOOL * stop) {
    NSLog(@"Element %d = %@", idx, obj);

    // To abort use:
    *stop = YES
}];

// Using block enumeration with options
[myColors enumerateWithOptions:NSEnumerationReverse usingBlock:^(id obj, NSUInteger idx, BOOL * stop) {
    NSLog(@"Element %d = %@", idx, obj);
}];
```

Using Generics

For added safety we can define the type of object that the array contains:

```
NSArray<NSString *> *colors = @[@"Red", @"Green", @"Blue", @"Yellow"];
NSMutableArray<NSString *> *myColors = [NSMutableArray arrayWithArray:colors];
[myColors addObject:@"Orange"]; // OK
[myColors addObject:[UIColor purpleColor]]; // "Incompatible pointer type" warning
```

It should be noted that this is checked during compilation time only.

Enumerating using blocks

```
NSArray *myColors = @[@"Red", @"Green", @"Blue", @"Yellow"];
[myColors enumerateObjectsUsingBlock:^(id obj, NSUInteger idx, BOOL *stop) {
    NSLog(@"enumerating object %@ at index %lu", obj, idx);
}];
```

By setting the `stop` parameter to `YES` you can indicate that further enumeration is not needed. to do this simply set `&stop = YES`.

NSEnumerationOptions

You can enumerate the array in reverse and / or concurrently :

```
[myColors enumerateObjectsWithOptions:NSEnumerationConcurrent | NSEnumerationReverse
        usingBlock:^(id obj, NSUInteger idx, BOOL *stop) {
            NSLog(@"enumerating object %@ at index %lu", obj, idx);
        }];
```

Enumerating subset of array

```
NSIndexSet *indexSet = [NSIndexSet indexSetWithIndexesInRange:NSMakeRange(1, 1)];
[myColors enumerateObjectsAtIndexes:indexSet
        options:kNilOptions
        usingBlock:^(id obj, NSUInteger idx, BOOL *stop) {
            NSLog(@"enumerating object %@ at index %lu", obj, idx);
        }];
```

Comparing arrays

Arrays can be compared for equality with the aptly named **isEqualToArray:** method, which returns **YES** when both arrays have the same number of elements and every pair pass an **isEqual:** comparison.

```
NSArray *germanMakes = @[@"Mercedes-Benz", @"BMW", @"Porsche",
                        @"Opel", @"Volkswagen", @"Audi"];
NSArray *sameGermanMakes = [NSArray arrayWithObjects:@"Mercedes-Benz",
                        @"BMW", @"Porsche", @"Opel",
                        @"Volkswagen", @"Audi", nil];

if ([germanMakes isEqualToArray:sameGermanMakes]) {
    NSLog(@"Oh good, literal arrays are the same as NSArray");
}
```

The important thing is every pair must pass the **isEqual:** test. For custom objects this method should be implemented. It exists in the **NSObject** protocol.

Add objects to NSArray

```
NSArray *a = @[a1];
a = [a arrayByAddingObject:a2];
a = [a arrayByAddingObjectsFromArray:[a3, a4, a5]];
```

These methods are optimized to recreate the new array very efficiently, usually without having to destroy the original array or even allocate more memory.

Read NSArray online: <https://riptutorial.com/objective-c/topic/736/nsarray>

Chapter 23: NSArray

Examples

Creating NSArray instances

```
NSArray *array1 = [NSArray arrayWithObjects:@"one", @"two", @"three", nil];
NSArray *array2 = @[@"one", @"two", @"three"];
```

Sorting Arrays

The most flexible ways to sort an array is with the `sortedArrayUsingComparator:` method. This accepts an **^NSComparisonResult(id obj1, id obj2) block**.

Return Value	Description
NSOrderedAscending	obj1 comes before obj2
NSOrderedSame	obj1 and obj2 have no order
NSOrderedDescending	obj1 comes after obj2

Example:

```
NSArray *categoryArray = @[@"Apps", @"Music", @"Songs",
                           @"iTunes", @"Books", @"Videos"];

NSArray *sortedArray = [categoryArray sortedArrayUsingComparator:
^NSComparisonResult(id obj1, id obj2) {
    if ([obj1 length] < [obj2 length]) {
        return NSOrderedAscending;
    } else if ([obj1 length] > [obj2 length]) {
        return NSOrderedDescending;
    } else {
        return NSOrderedSame;
    }
}];

NSLog(@"%@", sortedArray);
```

Filter NSArray and NSMutableArray

```
NSMutableArray *array =
    [NSMutableArray arrayWithObjects:@"Ken", @"Tim", @"Chris", @"Steve", @"Charlie", @"Melissa",
    nil];

NSPredicate *bPredicate =
    [NSPredicate predicateWithFormat:@"SELF beginswith[c] 'c'"];
NSArray *beginWithB =
    [array filteredArrayUsingPredicate:bPredicate];
// beginWith "C" contains { @"Chris", @"Charlie" }.

NSPredicate *sPredicate =
    [NSPredicate predicateWithFormat:@"SELF contains[c] 'a'"];
```

```
[array filterUsingPredicate:sPredicate];  
// array now contains { @"Charlie", @"Melissa" }
```

Read NSArray online: <https://riptutorial.com/objective-c/topic/1181/nsarray>

Chapter 24: NSAttributedString

Examples

Creating a string that has custom kerning (letter spacing) editshare

`NSAttributedString` (and its mutable sibling `NSMutableAttributedString`) allows you to create strings that are complex in their appearance to the user.

A common application is to use this to display a string and adding custom kerning / letter-spacing.

This would be achieved as follows (where `label` is a `UILabel`), giving a different kerning for the word "kerning"

```
NSMutableAttributedString *attributedString;
attributedString = [[NSMutableAttributedString alloc] initWithString:@"Apply kerning"];
[attributedString addAttribute:NSKernAttributeName value:@5 range:NSMakeRange(6, 7)];
[label setAttributedText:attributedString];
```

Create a string with text struck through

```
NSMutableAttributedString *attributeString = [[NSMutableAttributedString alloc]
initWithString:@"Your String here"];
[attributeString addAttribute:NSStrikethroughStyleAttributeName
                        value:@2
                        range:NSMakeRange(0, [attributeString length])];
```

Using Enumerating over Attributes in a String and underline part of string

```
NSMutableDictionary *attributesDictionary = [NSMutableDictionary dictionary];
[attributesDictionary setObject:[UIFont systemFontOfSize:14] forKey:NSFontAttributeName];
//[attributesDictionary setObject:[UIColor redColor] forKey:NSForegroundColorAttributeName];
NSMutableAttributedString *attributedString = [[NSMutableAttributedString
alloc] initWithString:@"Google www.google.com link" attributes:attributesDictionary];

[attributedString enumerateAttribute:(NSString *) NSFontAttributeName
                        inRange:NSMakeRange(0, [attributedString length])
                        options:NSAttributedStringEnumerationLongestEffectiveRangeNotRequired
                      usingBlock:^(id value, NSRange range, BOOL *stop) {
    NSLog(@"Attribute: %@, %@", value, NSStringFromRange(range));
}];

NSMutableAttributedString *attributedString = [[NSMutableAttributedString alloc]
initWithString:@"www.google.com "];

[attributedString addAttribute:NSUnderlineStyleAttributeName
                        value:[NSNumber numberWithInt:NSUnderlineStyleDouble]
                        range:NSMakeRange(7, attributedStr.length)];

[attributedString addAttribute:NSForegroundColorAttributeName
```

```
        value:[UIColor blueColor]
        range:NSMakeRange(6, attributedStr.length)];

    _attrLbl.attributedText = attributedString;//_attrLbl (of type UILabel) added in
storyboard
```

Output:

Google www.google.com link

How you create a tri-color attributed string.

```
NSMutableAttributedString * string = [[NSMutableAttributedString alloc]
initWithString:@"firstsecondthird"];
[string addAttribute:NSForegroundColorAttributeName value:[UIColor redColor]
range:NSMakeRange(0, 5)];
[string addAttribute:NSForegroundColorAttributeName value:[UIColor greenColor]
range:NSMakeRange(5, 6)];
[string addAttribute:NSForegroundColorAttributeName value:[UIColor blueColor]
range:NSMakeRange(11, 5)];
```

Range : start to end string

Here we have firstsecondthird string so in first we have set range (0,5) so from starting first character to fifth character it will display in green text color.

Read NSAttributedString online: <https://riptutorial.com/objective-c/topic/3725/nsattributedstring>

Chapter 25: NSCache

Examples

NSCache

You use it the same way you would use NSMutableDictionary. The difference is that when NSCache detects excessive memory pressure (i.e. it's caching too many values) it will release some of those values to make room.

If you can recreate those values at runtime (by downloading from the Internet, by doing calculations, whatever) then NSCache may suit your needs. If the data cannot be recreated (e.g. it's user input, it is time-sensitive, etc.) then you should not store it in an NSCache because it will be destroyed there.

Read NSCache online: <https://riptutorial.com/objective-c/topic/8257/nscache>

Chapter 26: NSCalendar

Examples

System Locale Information

`+currentCalendar` returns the logical calendar for the current user.

```
NSCalendar *calender = [NSCalendar currentCalendar];
NSLog(@"%@", calender);
```

`+autoupdatingCurrentCalendar` returns the current logical calendar for the current user.

```
NSCalendar *calender = [NSCalendar autoupdatingCurrentCalendar];
NSLog(@"%@", calender);
```

Initializing a Calendar

- `initWithCalendarIdentifier:` Initializes a newly-allocated `NSCalendar` object for the calendar specified by a given identifier.

```
NSCalendar *calender = [[NSCalendar alloc] initWithCalendarIdentifier:@"gregorian"];
NSLog(@"%@", calender);
```

- `setFirstWeekday:` Sets the index of the first weekday for the receiver.

```
NSCalendar *calender = [NSCalendar autoupdatingCurrentCalendar];
[calender setFirstWeekday:1];
NSLog(@"%d", [calender firstWeekday]);
```

- `setLocale:` Sets the locale for the receiver.

```
NSCalendar *calender = [NSCalendar autoupdatingCurrentCalendar];
[calender setLocale:[NSLocale currentLocale]];
NSLog(@"%@", [calender locale]);
```

- `setMinimumDaysInFirstWeek:` Sets the minimum number of days in the first week of the receiver.

```
NSCalendar *calender = [NSCalendar autoupdatingCurrentCalendar];
[calender setMinimumDaysInFirstWeek:7];
NSLog(@"%d", [calender minimumDaysInFirstWeek]);
```

- `setTimeZone:` Sets the time zone for the receiver.

```
NSCalendar *calender = [NSCalendar autoupdatingCurrentCalendar];
[calender setTimeZone:[NSTimeZone timeZoneForSecondsFromGMT:0]];
NSLog(@"%@", [calender timeZone]);
```

Calendrical Calculations

- `components:fromDate:` Returns a `NSDateComponents` object containing a given date decomposed into specified components

```
NSCalendar *calendar = [NSCalendar autoupdatingCurrentCalendar];
[calendar setTimeZone:[NSTimeZone timeZoneForSecondsFromGMT:0]];
NSLog(@"%@", [calendar components:NSCalendarUnitDay fromDate:[NSDate date]]);
NSLog(@"%@", [calendar components:NSCalendarUnitYear fromDate:[NSDate date]]);
NSLog(@"%@", [calendar components:NSCalendarUnitMonth fromDate:[NSDate date]]);
```

- `components:fromDate:toDate:options:` Returns, as an `NSDateComponents` object using specified components, the difference between two supplied dates.

```
NSCalendar *calendar = [NSCalendar autoupdatingCurrentCalendar];
[calendar setTimeZone:[NSTimeZone timeZoneForSecondsFromGMT:0]];
NSLog(@"%@", [calendar components:NSCalendarUnitYear fromDate:[NSDate
dateWithTimeIntervalSince1970:0] toDate:[NSDate dateWithTimeIntervalSinceNow:18000]
options:NSCalendarWrapComponents]);
```

- `dateByAddingComponents:toDate:options:` Returns a new `NSDate` object representing the absolute time calculated by adding given components to a given date.

```
NSCalendar *calendar = [NSCalendar autoupdatingCurrentCalendar];
NSDateComponents *dateComponent = [[NSDateComponents alloc] init];
[dateComponent setYear:10];
NSLog(@"%@", [calendar dateByAddingComponents:dateComponent toDate:[NSDate
dateWithTimeIntervalSinceNow:0] options:NSCalendarWrapComponents] );
```

- `dateFromComponents:` Returns a new `NSDate` object representing the absolute time calculated from given components.

```
NSCalendar *calendar = [NSCalendar autoupdatingCurrentCalendar];
NSDateComponents *dateComponent = [[NSDateComponents alloc] init];
[dateComponent setYear:2020];
NSLog(@"%@", [calendar dateFromComponents:dateComponent]);
```

Read `NSCalendar` online: <https://riptutorial.com/objective-c/topic/2903/nscalendar>

Chapter 27: NSData

Examples

Create

From NSString:

```
NSString *str = @"Hello world";
NSData *data = [str dataUsingEncoding:NSUTF8StringEncoding];
```

From Int:

```
int i = 1;
NSData *data = [NSData dataWithBytes: &i length: sizeof(i)];
```

You can also use the following methods:

```
+ initWithContentsOfURL:
+ initWithContentsOfURL:options:error:
+ initWithData:
- initWithBase64EncodedData:options:
- initWithBase64EncodedString:options:
- initWithBase64Encoding:
- initWithBytesNoCopy:length:
- initWithBytesNoCopy:length:deallocator:
- initWithBytesNoCopy:length:freeWhenDone:
- initWithContentsOfFile:
- initWithContentsOfFile:options:error:
- initWithContentsOfMappedFile:
- initWithContentsOfURL:
- initWithContentsOfURL:options:error:
- initWithData:
```

Get NSData length

```
NSString *filePath = [[NSFileManager defaultManager] pathForResource:@"data" ofType:@"txt"];
NSData *data = [NSData dataWithContentsOfFile:filePath];
int len = [data length];
```

Encoding and decoding a string using NSData Base64

Encoding

```
//Create a Base64 Encoded NSString Object
NSData *nsdata = [@"iOS Developer Tips encoded in Base64"
dataUsingEncoding:NSUTF8StringEncoding];

// Get NSString from NSData object in Base64
```

```

NSString *base64Encoded = [NSData base64EncodedStringWithOptions:0];
// Print the Base64 encoded string
NSLog(@"Encoded: %@", base64Encoded);

```

Decoding:

```

// NSData from the Base64 encoded str
NSData *nsdataFromBase64String = [[NSData alloc] initWithBase64EncodedString:base64Encoded
options:0];

// Decoded NSString from the NSData
NSString *base64Decoded = [[NSString alloc] initWithData:nsdataFromBase64String
encoding:NSUTF8StringEncoding];
NSLog(@"Decoded: %@", base64Decoded);

```

NSData and Hexadecimal String

Get NSData from Hexadecimal String

```

+ (NSData *)dataFromHexString:(NSString *)string
{
    string = [string lowercaseString];
    NSMutableData *data= [NSMutableData new];
    unsigned char whole_byte;
    char byte_chars[3] = {'\0', '\0', '\0'};
    int i = 0;
    int length = (int) string.length;
    while (i < length-1) {
        char c = [string characterAtIndex:i++];
        if (c < '0' || (c > '9' && c < 'a') || c > 'f')
            continue;
        byte_chars[0] = c;
        byte_chars[1] = [string characterAtIndex:i++];
        whole_byte = strtoul(byte_chars, NULL, 16);
        [data appendBytes:&whole_byte length:1];
    }
    return data;
}

```

Get Hexadecimal String from data:

```

+ (NSString *)hexStringForData:(NSData *)data
{
    if (data == nil) {
        return nil;
    }

    NSMutableString *hexString = [NSMutableString string];

    const unsigned char *p = [data bytes];

    for (int i=0; i < [data length]; i++) {
        [hexString appendFormat:@"%02x", *p++];
    }

    return hexString;
}

```

```
}
```

Read NSData online: <https://riptutorial.com/objective-c/topic/1532/nsdata>

Chapter 28: NSDate

Remarks

`NSDate` is a very simple value type, representing one exact moment in universal time. It does not contain information about time zones, daylight saving time, calendars, or locale.

`NSDate` is really only an immutable wrapper around an `NSTimeInterval` which is a `double`. There is no mutable subclass, as with some other value types in Foundation.

Examples

Creating an NSDate

The `NSDate` class provides methods for creating `NSDate` objects corresponding to a given date and time. An `NSDate` can be initialized using the designated initializer, which:

Returns an `NSDate` object initialized relative to 00:00:00 UTC on 1 January 2001 by a given number of seconds.

```
NSDate *date = [[NSDate alloc] initWithTimeIntervalSinceReferenceDate:100.0];
```

`NSDate` also provides an easy way to create an `NSDate` equal to the current date and time:

```
NSDate *now = [NSDate date];
```

It is also possible to create an `NSDate` a given amount of seconds from the current date and time:

```
NSDate *tenSecondsFromNow = [NSDate dateWithTimeIntervalSinceNow:10.0];
```

Date Comparison

There are 4 methods for comparing `NSDate`s in Objective-C:

- - (BOOL)isEqualToDate:(NSDate *)anotherDate
- - (NSDate *)earlierDate:(NSDate *)anotherDate
- - (NSDate *)laterDate:(NSDate *)anotherDate
- - (NSComparisonResult)compare:(NSDate *)anotherDate

Consider the following example using 2 dates, `NSDate date1 = July 7, 2016` and `NSDate date2 = July 2, 2016`:

```
NSDateComponents *comps1 = [[NSDateComponents alloc] init];  
comps1.year = 2016;  
comps1.month = 7;  
comps1.day = 7;
```

```
NSDateComponents *comps2 = [[NSDateComponents alloc] init];
comps.year = 2016;
comps.month = 7;
comps.day = 2;

NSDate* date1 = [calendar dateFromComponents:comps1]; //Initialized as July 7, 2016
NSDate* date2 = [calendar dateFromComponents:comps2]; //Initialized as July 2, 2016
```

Now that the `NSDate`s are created, they can be compared:

```
if ([date1 isEqualToDate:date2]) {
    //Here it returns false, as both dates are not equal
}
```

We can also use the `earlierDate:` and `laterDate:` methods of the `NSDate` class:

```
NSDate *earlierDate = [date1 earlierDate:date2]; //Returns the earlier of 2 dates. Here
earlierDate will equal date2.
NSDate *laterDate = [date1 laterDate:date2]; //Returns the later of 2 dates. Here laterDate
will equal date1.
```

Lastly, we can use `NSDate`'s `compare:` method:

```
NSComparisonResult result = [date1 compare:date2];
if (result == NSOrderedAscending) {
    //Fails
    //Comes here if date1 is earlier than date2. In our case it will not come here.
}else if (result == NSOrderedSame){
    //Fails
    //Comes here if date1 is the same as date2. In our case it will not come here.
}else{//NSOrderedDescending

    //Succeeds
    //Comes here if date1 is later than date2. In our case it will come here
}
```

Convert `NSDate` that is composed from hour and minute (only) to a full `NSDate`

There are many cases when one has created an `NSDate` from only an hour and minute format, i.e: 08:12

The downside for this situation is that your `NSDate` is almost completely "naked" and what you need to do is to create: day, month, year, second and time zone in order to this object to "play along" with other `NSDate` types.

For the sake of the example let's say that `hourAndMinute` is the `NSDate` type that is composed from hour and minute format:

```
NSDateComponents *hourAndMintuteComponents = [calendar components:NSCalendarUnitHour |
NSCalendarUnitMinute
                                                fromDate:hourAndMinute];
```

```

NSDateComponents *componentsOfDate = [[NSCalendar currentCalendar]
components:NSCalendarUnitDay | NSCalendarUnitMonth | NSCalendarUnitYear
                                             fromDate:[NSDate date]];

NSDateComponents *components = [[NSDateComponents alloc] init];
[components setDay: componentsOfDate.day];
[components setMonth: componentsOfDate.month];
[components setYear: componentsOfDate.year];
[components setHour: [hourAndMinuteComponents hour]];
[components setMinute: [hourAndMinuteComponents minute]];
[components setSecond: 0];
[calendar setTimeZone: [NSTimeZone defaultTimeZone]];

NSDate *yourFullNSDateObject = [calendar dateFromComponents:components];

```

Now your object is the total opposite of being "naked".

Converting NSDate to NSString

If we have an NSDate object, and we want to convert it into NSString. There are different types of Date strings. How we can do that?, It is very simple. Just 3 steps.

1. Create NSDateFormatter Object

```
NSDateFormatter *dateFormatter = [[NSDateFormatter alloc] init];
```

2. Set the date format in which you want your string.

```
dateFormatter.dateFormat = @"yyyy-MM-dd 'at' HH:mm";
```

3. Now, get the formatted string

```

NSDate *date = [NSDate date]; // your NSDate object
NSString *dateString = [dateFormatter stringFromDate:date];

```

This will give output something like this: 2001-01-02 at 13:00

Note:

Creating an NSDateFormatter instance is an expensive operation, so it is recommended to create it once and reuse when possible.

Read NSDate online: <https://riptutorial.com/objective-c/topic/1981/nsdate>

Chapter 29: NSDictionary

Examples

Create

```
NSDictionary *dict = [[NSDictionary alloc] initWithObjectsAndKeys:@"value1", @"key1",  
@"value2", @"key2", nil];
```

or

```
NSArray *keys = [NSArray arrayWithObjects:@"key1", @"key2", nil];  
NSArray *objects = [NSArray arrayWithObjects:@"value1", @"value2", nil];  
NSDictionary *dictionary = [NSDictionary dictionaryWithObjects:objects  
forKeys:keys];
```

or using appropriate literal syntax

```
NSDictionary *dict = @{@"key": @"value", @"nextKey": @"nextValue"};
```

NSDictionary to NSArray

```
NSDictionary *myDictionary = [[NSDictionary alloc] initWithObjectsAndKeys:@"value1", @"key1",  
@"value2", @"key2", nil];  
NSArray *copiedArray = myDictionary.copy;
```

Get keys:

```
NSArray *keys = [myDictionary allKeys];
```

Get values:

```
NSArray *values = [myDictionary allValues];
```

NSDictionary to NSData

```
NSDictionary *myDictionary = [[NSDictionary alloc] initWithObjectsAndKeys:@"value1", @"key1",  
@"value2", @"key2", nil];  
NSData *myData = [NSKeyedArchiver archivedDataWithRootObject:myDictionary];
```

Reverse path:

```
NSDictionary *myDictionary = (NSDictionary*) [NSKeyedUnarchiver  
unarchiveObjectWithData:myData];
```

NSDictionary to JSON

```
NSDictionary *myDictionary = [[NSDictionary alloc] initWithObjectsAndKeys:@"value1", @"key1",
@"value2", @"key2", nil];

NSMutableDictionary *mutableDictionary = [myDictionary mutableCopy];
NSData *data = [NSJSONSerialization dataWithJSONObject:myDictionary
options:NSJSONWritingPrettyPrinted error:nil];
NSString *jsonString = [[NSString alloc] initWithData:data encoding:NSUTF8StringEncoding];
```

Block Based Enumeration

Enumerating dictionaries allows you to run a block of code on each dictionary key-value pair using the method `enumerateKeysAndObjectsUsingBlock:(void (^)(id key, id obj, BOOL *stop))block`

Example:

```
NSDictionary stockSymbolsDictionary = @{
    @"AAPL": @"Apple",
    @"GOOGL": @"Alphabet",
    @"MSFT": @"Microsoft",
    @"AMZN": @"Amazon"
};

NSLog(@"Printing contents of dictionary via enumeration");
[stockSymbolsDictionary enumerateKeysAndObjectsUsingBlock:^(id key, id obj, BOOL *stop) {
    NSLog(@"Key: %@, Value: %@", key, obj);
}];
```

Fast Enumeration

`NSDictionary` can be enumerated using fast enumeration, just like other collection types:

```
NSDictionary stockSymbolsDictionary = @{
    @"AAPL": @"Apple",
    @"GOOGL": @"Alphabet",
    @"MSFT": @"Microsoft",
    @"AMZN": @"Amazon"
};

for (id key in stockSymbolsDictionary)
{
    id value = dictionary[key];
    NSLog(@"Key: %@, Value: %@", key, value);
}
```

Because `NSDictionary` is inherently unordered, the order of keys that in the for loop is not guaranteed.

Read `NSDictionary` online: <https://riptutorial.com/objective-c/topic/847/nsdictionary>

Chapter 30: NSDictionary

Syntax

- `@{ key: value, ... }`
- `[NSDictionary dictionaryWithObjectsAndKeys: value, key, ..., nil];`
- `dict[key] = value;`
- `id value = dict[key];`

Remarks

The NSDictionary class declares the programmatic interface to objects that manage immutable associations of keys and values. Use this class or its subclass NSMutableDictionary when you need a convenient and efficient way to retrieve data associated with an arbitrary key. NSDictionary creates static dictionaries, and NSMutableDictionary creates dynamic dictionaries. (For convenience, the term dictionary refers to any instance of one of these classes without specifying its exact class membership.)

A key-value pair within a dictionary is called an entry. Each entry consists of one object that represents the key and a second object that is that key's value. Within a dictionary, the keys are unique. That is, no two keys in a single dictionary are equal (as determined by isEqual:). In general, a key can be any object (provided that it conforms to the NSCopying protocol—see below), but note that when using key-value coding the key must be a string (see Key-Value Coding Fundamentals). Neither a key nor a value can be nil; if you need to represent a null value in a dictionary, you should use NSNull.

NSDictionary is “toll-free bridged” with its Core Foundation counterpart, CFDictionaryRef. See Toll-Free Bridging for more information on toll-free bridging.

Examples

Creating using literals

```
NSDictionary *inventory = @{
    @"Mercedes-Benz SLK250" : @(13),
    @"BMW M3 Coupe" : @(self.BMWM3CoupeInventory.count),
    @"Last Updated" : @"Jul 21, 2016",
    @"Next Update" : self.nextInventoryUpdateString
};
```

Creating using dictionaryWithObjectsAndKeys:

```
NSDictionary *inventory = [NSDictionary dictionaryWithObjectsAndKeys:
    [NSNumber numberWithInt:13], @"Mercedes-Benz SLK250",
    [NSNumber numberWithInt:22], @"Mercedes-Benz E350",
    [NSNumber numberWithInt:19], @"BMW M3 Coupe",
    [NSNumber numberWithInt:16], @"BMW X6",
    nil];
```

`nil` must be passed as the last parameter as a sentinel signifying the end.

It's important to remember that when instantiating dictionaries this way the values go first and the keys second. In the example above the strings are the keys and the numbers are the values. The method's name reflects this too: `dictionaryWithObjectsAndKeys`. While this is not incorrect, the more modern way of instantiating dictionaries (with literals) is preferred.

Creating using plists

```
NSString *pathToPlist = [[NSBundle mainBundle] pathForResource:@"plistName"
    ofType:@"plist"];
NSDictionary *plistDict = [[NSDictionary alloc] initWithContentsOfFile:pathToPlist];
```

Setting a Value in NSDictionary

There are multiple ways to set a key's object in an `NSDictionary`, corresponding to the ways you get a value. For instance, to add a lamborghini to a list of cars

Standard

```
[cars setObject:lamborghini forKey:@"Lamborghini"];
```

Just like any other object, call the method of `NSDictionary` that sets an object of a key, `objectForKey:`. Be careful not to confuse this with `setValue:forKey:`; that's for a completely different thing, [Key Value Coding](#)

Shorthand

```
cars[@"Lamborghini"] = lamborghini;
```

This is the syntax that you use for dictionaries in most other languages, such as C#, Java, and Javascript. It's much more convenient than the standard syntax, and arguably more readable (especially if you code in these other languages), but of course, it isn't *standard*. It's also only available in newer versions of Objective C

Getting a Value from NSDictionary

There are multiple ways to get an object from an `NSDictionary` with a key. For instance, to get a lamborghini from a list of cars

Standard

```
Car * lamborghini = [cars objectForKey:@"Lamborghini"];
```

Just like any other object, call the method of NSDictionary that gives you an object for a key, `objectForKey:`. Be careful not to confuse this with `valueForKey:`; that's for a completely different thing, [Key Value Coding](#)

Shorthand

```
Car * lamborghini = cars[@"Lamborghini"];
```

This is the syntax that you use for dictionaries in most other languages, such as C#, Java, and Javascript. It's much more convenient than the standard syntax, and arguably more readable (especially if you code in these other languages), but of course, it isn't *standard*. It's also only available in newer versions of Objective C

Check if NSDictionary already has a key or not

Objective c:

```
//this is the dictionary you start with.
NSDictionary *dict = [NSDictionary dictionaryWithObjectsAndKeys:@"name1", @"Sam",@"name2",
@"Sanju",nil];

//check if the dictionary contains the key you are going to modify. In this example, @"Sam"
if (dict[@"name1"] != nil) {
    //there is an entry for Key name1
}
else {
    //There is no entry for name1
}
```

Read NSDictionary online: <https://riptutorial.com/objective-c/topic/875/nsdictionary>

Chapter 31: NSJSONSerialization

Syntax

- (id)JSONObjectWithData:(NSData *)data options:(NSJSONReadingOptions)opt error:(NSError * _Nullable *)error

Parameters

Operator	Description
data	A data object containing JSON data
opt	Options for reading the JSON data and creating the Foundation objects.
error	If an error occurs, upon return contains an NSError object that describes the problem.

Remarks

NSJSONSerialization is Available in iOS 5.0 and later An object that may be converted to JSON must have the following properties:

- The top level object is an NSArray or NSDictionary.
- All objects are instances of NSString, NSNumber, NSArray, NSDictionary, or NSNull.
- All dictionary keys are instances of NSString.
- Numbers are not NaN or infinity.

Examples

JSON Parsing using NSJSONSerialization Objective c

```
NSError *e = nil;
NSString *jsonString = @"[{\"id\": \"1\", \"name\": \"sam\"}]";
NSData *data = [jsonString dataUsingEncoding:NSUTF8StringEncoding];

NSArray *jsonArray = [NSJSONSerialization JSONObjectWithData: data options:
NSJSONReadingMutableContainers error: &e];

if (!jsonArray) {
    NSLog(@"Error parsing JSON: %@", e);
} else {
    for(NSDictionary *item in jsonArray) {
        NSLog(@"Item: %@", item);
    }
}
```

```
}  
}
```

Output:

```
Item: {  
    id = 1;  
    name = sam;  
}
```

Example 2:Using contents of url:

```
//Parsing:  
  
NSData *data = [NSData dataWithContentsOfURL:@"URL HERE"];  
NSError *error;  
NSDictionary *json = [NSJSONSerialization JSONObjectWithData:data options:kNilOptions  
error:&error];  
NSLog(@"json :%@", json);
```

Sample response:

```
json: {  
    MESSAGE = "Test Message";  
    RESPONSE =(  
        {  
            email = "test@gmail.com";  
            id = 15;  
            phone = 1234567890;  
            name = Staffy;  
        }  
    );  
    STATUS = SUCCESS;  
}  
  
NSMutableDictionary *response = [[[json valueForKey:@"RESPONSE"]  
objectAtIndex:0]mutableCopy];  
NSString *nameStr = [response valueForKey:@"name"];  
NSString *emailIdStr = [response valueForKey:@"email"];
```

Read NSJSONSerialization online: <https://riptutorial.com/objective-c/topic/2587/nsjsonserialization>

Chapter 32: NSMutableArray

Examples

Adding elements

```
NSMutableArray *myColors;
myColors = [NSMutableArray arrayWithObjects: @"Red", @"Green", @"Blue", @"Yellow", nil];
[myColors addObject: @"Indigo"];
[myColors addObject: @"Violet"];

//Add objects from an NSArray
NSArray *myArray = @[@"Purple",@"Orange"];
[myColors addObjectsFromArray:myArray];
```

Insert Elements

```
NSMutableArray *myColors;
int i;
int count;
myColors = [NSMutableArray arrayWithObjects: @"Red", @"Green", @"Blue", @"Yellow", nil];
[myColors insertObject: @"Indigo" atIndex: 1];
[myColors insertObject: @"Violet" atIndex: 3];
```

Deleting Elements

Remove at specific index:

```
[myColors removeObjectAtIndex: 3];
```

Remove the first instance of a specific object:

```
[myColors removeObject: @"Red"];
```

Remove all instances of a specific object:

```
[myColors removeObjectIdenticalTo: @"Red"];
```

Remove all objects:

```
[myColors removeAllObjects];
```

Remove last object:

```
[myColors removeLastObject];
```

Sorting Arrays

```
NSMutableArray *myColors = [NSMutableArray arrayWithObjects: @"red", @"green", @"blue",
@"yellow", nil];
NSArray *sortedArray;
sortedArray = [myColors sortedArrayUsingSelector:@selector(localizedCaseInsensitiveCompare:)];
```

Move object to another index

Move *Blue* to the beginning of the array:

```
NSMutableArray *myColors = [NSMutableArray arrayWithObjects: @"Red", @"Green", @"Blue",
@"Yellow", nil];

NSUInteger fromIndex = 2;
NSUInteger toIndex = 0;

id blue = [[[self.array objectAtIndex:fromIndex] retain] autorelease];
[self.array removeObjectAtIndex:fromIndex];
[self.array insertObject:blue atIndex:toIndex];
```

myColors is now ["Blue", @"Red", @"Green", @"Yellow"].

Filtering Array content with Predicate

Using **filterUsingPredicate**: This Evaluates a given predicate against the arrays content and return objects that match.

Example:

```
NSMutableArray *array = [NSMutableArray array];
[array setArray:@[@"iOS",@"macOS",@"tvOS"]];
NSPredicate *predicate = [NSPredicate predicateWithFormat:@"SELF beginswith[c] 'i'"];
NSArray *resultArray = [array filteredArrayUsingPredicate:predicate];
NSLog(@"%@",resultArray);
```

Creating an NSMutableArray

NSMutableArray can be initialized as an empty array like this:

```
NSMutableArray *array = [[NSMutableArray alloc] init];
// or
NSMutableArray *array2 = @[].mutableCopy;
// or
NSMutableArray *array3 = [NSMutableArray array];
```

NSMutableArray can be initialized with another array like this:

```
NSMutableArray *array4 = [[NSMutableArray alloc] initWithArray:anotherArray];
// or
NSMutableArray *array5 = anotherArray.mutableCopy;
```

Read NSMutableArray online: <https://riptutorial.com/objective-c/topic/2008/nsmutablearray>

Chapter 33: NSMutableDictionary

Parameters

objects	keys
An array containing the values for the new dictionary.	CellAn array containing the keys for the new dictionary. Each key is copied and the copy is added to the dictionary.

Examples

NSMutableDictionary Example

+ dictionaryWithCapacity:

Creates and returns a mutable dictionary, initially giving it enough allocated memory to hold a given number of entries.

```
NSMutableDictionary *dict = [NSMutableDictionary dictionaryWithCapacity:1];
NSLog(@"%@", dict);
```

- init

Initializes a newly allocated mutable dictionary.

```
NSMutableDictionary *dict = [[NSMutableDictionary alloc] init];
NSLog(@"%@", dict);
```

+ dictionaryWithSharedKeySet:

Creates a mutable dictionary which is optimized for dealing with a known set of keys.

```
id sharedKeySet = [NSDictionary sharedKeySetForKeys:@[@"key1", @"key2"]]; // returns
NSMutableDictionary *dict = [NSMutableDictionary dictionaryWithSharedKeySet:sharedKeySet];
dict[@"key1"] = @"Easy";
dict[@"key2"] = @"Tutorial";
//We can an object thats not in the shared keyset
dict[@"key3"] = @"Website";
NSLog(@"%@", dict);
```

OUTPUT

```
{
    key1 = Eezy;
    key2 = Tutorials;
    key3 = Website;
```

```
}
```

Adding Entries to a Mutable Dictionary

- setObject:forKey:

Adds a given key-value pair to the dictionary.

```
NSMutableDictionary *dict = [NSMutableDictionary dictionary];  
[dict setObject:@"Easy" forKey:@"Key1"];  
NSLog(@"%@", dict);
```

OUTPUT

```
{  
    Key1 = Easy;  
}
```

- setObject:forKeyedSubscript:

Adds a given key-value pair to the dictionary.

```
NSMutableDictionary *dict = [NSMutableDictionary dictionary];  
[dict setObject:@"Easy" forKeyedSubscript:@"Key1"];  
NSLog(@"%@", dict);
```

OUTPUT { Key1 = Easy; }

Removing Entries From a Mutable Dictionary

- removeObjectForKey:

Removes a given key and its associated value from the dictionary.

```
NSMutableDictionary *dict = [NSMutableDictionary  
dictionaryWithDictionary:@{@"key1":@"Easy",@"key2": @"Tutorials"}];  
[dict removeObjectForKey:@"key1"];  
NSLog(@"%@", dict);
```

OUTPUT

```
{  
    key2 = Tutorials;  
}
```

- removeAllObjects

Empties the dictionary of its entries.

```
NSMutableDictionary *dict = [NSMutableDictionary  
dictionaryWithDictionary:@{@"key1":@"Easy",@"key2": @"Tutorials"}];  
[dict removeAllObjects];  
NSLog(@"%@",dict);
```

OUTPUT

```
{  
}
```

- removeObjectForKey:

Removes from the dictionary entries specified by elements in a given array.

```
NSMutableDictionary *dict = [NSMutableDictionary  
dictionaryWithDictionary:@{@"key1":@"Easy",@"key2": @"Tutorials"}];  
[dict removeObjectForKey:@"key1"];  
NSLog(@"%@",dict);
```

OUTPUT

```
{  
    key2 = Tutorials;  
}
```

Read NSMutableDictionary online: <https://riptutorial.com/objective-c/topic/3103/nsmutabledictionary>

Chapter 34: NSObject

Introduction

`NSObject` is the root class of `Cocoa`, however the `Objective-C` language itself does not define any root classes at all its define by `Cocoa`, Apple's Framework. This root class of most `Objective-C` class hierarchies, from which subclasses inherit a basic interface to the runtime system and the ability to behave as `Objective-C` objects.

This class have all basic property of `Objective-C` class object like:

`self`.

`class` (name of the class).

`superclass` (superclass of current class).

Syntax

- `self`
- `superclass`
- `init`
- `alloc`
- `new`
- `isEqual`
- `isKindOfClass`
- `isMemberOfClass`
- `description`

Examples

NSObject

`@interface NSString : NSObject` (`NSObject` is a base class of `NSString` class).

You can use below methods for allocation of string class:

```
- (instancetype) init
+ (instancetype) new
+ (instancetype) alloc
```

For Copy any object :

```
- (id) copy;
```

```
- (id)mutableCopy;
```

For compare objects :

```
- (BOOL)isEqual:(id) object
```

To get superclass of current class :

```
superclass
```

To check which kind of class is this ?

```
- (BOOL)isKindOfClass:(Class) aClass
```

Some property of NON-ARC classes:

```
- (instancetype)retain OBJC_ARC_UNAVAILABLE;  
- (oneway void)release OBJC_ARC_UNAVAILABLE;  
- (instancetype)autorelease OBJC_ARC_UNAVAILABLE;  
- (NSUInteger)retainCount
```

Read NSObject online: <https://riptutorial.com/objective-c/topic/9355/nsobject>

Chapter 35: NSPredicate

Syntax

- **CONTAINS operator** : It allows to filter objects with matching subset.

```
NSPredicate *filterByName = [NSPredicate predicateWithFormat:@"self.title CONTAINS[cd] %@", @"Tom"];
```

- **LIKE** : Its simple comparison filter.

```
NSPredicate *filterByNameCIS = [NSPredicate predicateWithFormat:@"self.title LIKE[cd] %@", @"Tom and Jerry"];
```

- **= operator** : It returns all the objects with matching filter value.

```
NSPredicate *filterByNameCS = [NSPredicate predicateWithFormat:@"self.title = %@", @"Tom and Jerry"];
```

- **IN operator** : It allows you to filter objects with specific filter set.

```
NSPredicate *filterByIds = [NSPredicate predicateWithFormat:@"self.id IN %@", @[@"7CDF6D22-8D36-49C2-84FE-E31EECCECB79", @"7CDF6D22-8D36-49C2-84FE-E31EECCECB76"]];
```

- **NOT IN operator** : It allows you to find Inverse objects with specific set.

```
NSPredicate *filterByNotInIds = [NSPredicate predicateWithFormat:@"NOT (self.id IN %@", @[@"7CDF6D22-8D36-49C2-84FE-E31EECCECB79", @"7CDF6D22-8D36-49C2-84FE-E31EECCECB76"]];
```

Remarks

For more details read [NSPredicate in Apple documentation](#)

Examples

Filter By Name

```
NSArray *array = @[
    @{
        @"id": @"7CDF6D22-8D36-49C2-84FE-E31EECCECB71",
        @"title": @"Jackie Chan Strike Movie",
        @"url": @"http://abc.com/playback.m3u8",
        @"thumbnailURL": @"http://abc.com/thumbnail.png",
        @"isMovie" : @1
    },
    @{
        @"id": @"7CDF6D22-8D36-49C2-84FE-E31EECCECB72",
        @"title": @"Sherlock homes",
        @"url": @"http://abc.com/playback.m3u8",
        @"thumbnailURL": @"http://abc.com/thumbnail.png",
        @"isMovie" : @0
    },
];
```

```

    @{
        @"id": @"7CDF6D22-8D36-49C2-84FE-E31EECCECB73",
        @"title": @"Titanic",
        @"url": @"http://abc.com/playback.m3u8",
        @"thumbnailURL": @"http://abc.com/thumbnail.png",
        @"isMovie" : @1
    },
    @{
        @"id": @"7CDF6D22-8D36-49C2-84FE-E31EECCECB74",
        @"title": @"Star Wars",
        @"url": @"http://abc.com/playback.m3u8",
        @"thumbnailURL": @"http://abc.com/thumbnail.png",
        @"isMovie" : @1
    },
    @{
        @"id": @"7CDF6D22-8D36-49C2-84FE-E31EECCECB75",
        @"title": @"Pokemon",
        @"url": @"http://abc.com/playback.m3u8",
        @"thumbnailURL": @"http://abc.com/thumbnail.png",
        @"isMovie" : @0
    },
    @{
        @"id": @"7CDF6D22-8D36-49C2-84FE-E31EECCECB76",
        @"title": @"Avatar",
        @"url": @"http://abc.com/playback.m3u8",
        @"thumbnailURL": @"http://abc.com/thumbnail.png",
        @"isMovie" : @1
    },
    @{
        @"id": @"7CDF6D22-8D36-49C2-84FE-E31EECCECB77",
        @"title": @"Popey",
        @"url": @"http://abc.com/playback.m3u8",
        @"thumbnailURL": @"http://abc.com/thumbnail.png",
        @"isMovie" : @1
    },
    @{
        @"id": @"7CDF6D22-8D36-49C2-84FE-E31EECCECB78",
        @"title": @"Tom and Jerry",
        @"url": @"http://abc.com/playback.m3u8",
        @"thumbnailURL": @"http://abc.com/thumbnail.png",
        @"isMovie" : @1
    },
    @{
        @"id": @"7CDF6D22-8D36-49C2-84FE-E31EECCECB79",
        @"title": @"The wolf",
        @"url": @"http://abc.com/playback.m3u8",
        @"thumbnailURL": @"http://abc.com/thumbnail.png",
        @"isMovie" : @1
    }
}

];

// *** Case Insensitive comparison with exact title match ***
NSPredicate *filterByNameCIS = [NSPredicate predicateWithFormat:@"self.title LIKE[cd]
%@", @"Tom and Jerry"];
NSLog(@"Filter By Name (CIS) : %@", [array filteredArrayUsingPredicate:filterByNameCIS]);

```

Find movies except given ids

```

// *** Find movies except given ids ***

```

```

NSPredicate *filterByNotInIds = [NSPredicate predicateWithFormat:@"NOT (self.id IN
%@", @[@"7CDF6D22-8D36-49C2-84FE-E31EECCECB79", @"7CDF6D22-8D36-49C2-84FE-E31EECCECB76"]];
NSLog(@"Filter movies except given Ids : %@", [array
filteredArrayUsingPredicate:filterByNotInIds]);

```

Find all the objects which is of type movie

```

// *** Find all the objects which is of type movie, Both the syntax are valid ***
NSPredicate *filterByMovieType = [NSPredicate predicateWithFormat:@"self.isMovie = %@", @1];
// OR
//NSPredicate *filterByMovieType = [NSPredicate predicateWithFormat:@"self.isMovie =
%@", [NSNumber numberWithInt:YES]];
NSLog(@"Filter By Movie Type : %@", [array filteredArrayUsingPredicate:filterByMovieType]);

```

Find Distinct object ids of array

```

// *** Find Distinct object ids of array ***
NSLog(@"Distinct id : %@", [array valueForKeyPath:@"@distinctUnionOfObjects.id"]);

```

Find movies with specific ids

```

// *** Find movies with specific ids ***
NSPredicate *filterByIds = [NSPredicate predicateWithFormat:@"self.id IN %@", @[@"7CDF6D22-
8D36-49C2-84FE-E31EECCECB79", @"7CDF6D22-8D36-49C2-84FE-E31EECCECB76"]];
NSLog(@"Filter By Ids : %@", [array filteredArrayUsingPredicate:filterByIds]);

```

Case Insensitive comparison with exact title match

```

// *** Case Insensitive comparison with exact title match ***
NSPredicate *filterByNameCIS = [NSPredicate predicateWithFormat:@"self.title LIKE[cd]
%@", @"Tom and Jerry"];
NSLog(@"Filter By Name (CIS) : %@", [array filteredArrayUsingPredicate:filterByNameCIS]);

```

Case sensitive with exact title match

```

// *** Case sensitive with exact title match ***
NSPredicate *filterByNameCS = [NSPredicate predicateWithFormat:@"self.title = %@", @"Tom and
Jerry"];
NSLog(@"Filter By Name (CS) : %@", [array filteredArrayUsingPredicate:filterByNameCS]);

```

Case Insensitive comparison with matching subset

```

// *** Case Insensitive comparison with matching subset ***
NSPredicate *filterByName = [NSPredicate predicateWithFormat:@"self.title CONTAINS[cd]
%@", @"Tom"];
NSLog(@"Filter By Containing Name : %@", [array filteredArrayUsingPredicate:filterByName]);

```

Read NSPredicate online: <https://riptutorial.com/objective-c/topic/2004/npredicate>

Chapter 36: NSRegularExpression

Syntax

- `NSRegularExpression *regex = [NSRegularExpression regularExpressionWithPattern:PATTERN options:OPTIONS error:ERROR];`
- `NSArray<NSTextCheckingResult *> *results = [regex matchesInString:STRING options:OPTIONS range:RANGE_IN_STRING];`
- `NSInteger numberOfMatches = [regex numberOfMatchesInString:STRING options:OPTIONS range:RANGE_IN_STRING];`

Examples

Find all the numbers in a string

```
NSString *testString = @"There are 42 sheep and 8672 cows.";
NSError *error = nil;
NSRegularExpression *regex = [NSRegularExpression regularExpressionWithPattern:@"(\\d+)"
options:NSRegularExpressionCaseInsensitive
error:&error];

NSArray *matches = [regex matchesInString:testString
options:0
range:NSMakeRange(0, testString.length)];

for (NSTextCheckingResult *matchResult in matches) {
    NSString* match = [testString substringWithRange:matchResult.range];
    NSLog(@"match: %@", match);
}
```

The output will be `match: 42` and `match: 8672`.

Check whether a string matches a pattern

```
NSString *testString1 = @"(555) 123-5678";
NSString *testString2 = @"not a phone number";

NSError *error = nil;
NSRegularExpression *regex = [NSRegularExpression regularExpressionWithPattern:@"^\\(\\d{3}\\)\\d{3}\\-\\d{4}$"
options:NSRegularExpressionCaseInsensitive error:&error];

NSInteger result1 = [regex numberOfMatchesInString:testString1 options:0 range:NSMakeRange(0, testString1.length)];
NSInteger result2 = [regex numberOfMatchesInString:testString2 options:0 range:NSMakeRange(0, testString2.length)];

NSLog(@"Is string 1 a phone number? %@", result1 > 0 ? @"YES" : @"NO");
NSLog(@"Is string 2 a phone number? %@", result2 > 0 ? @"YES" : @"NO");
```

The output will show that the first string is a phone number and the second one isn't.

Read `NSRegularExpression` online: <https://riptutorial.com/objective-c/topic/2484/nsregularexpression>

Chapter 37: NSSortDescriptor

Examples

Sorted by combinations of NSSortDescriptor

```
NSArray *aryFName = @[ @"Alice", @"Bob", @"Charlie", @"Quentin" ];
NSArray *aryLName = @[ @"Smith", @"Jones", @"Smith", @"Alberts" ];
NSArray *aryAge = @[ @24, @27, @33, @31 ];

//Create a Custom class with properties for firstName & lastName of type NSString *,
//and age, which is an NSUInteger.

NSMutableArray *aryPerson = [NSMutableArray array];
[firstNames enumerateObjectsUsingBlock:^(id obj, NSUInteger idx, BOOL *stop) {
    Person *person = [[Person alloc] init];
    person.firstName = [aryFName objectAtIndex:idx];
    person.lastName = [aryLName objectAtIndex:idx];
    person.age = [aryAge objectAtIndex:idx];
    [aryPerson addObject:person];
}];

NSSortDescriptor *firstNameSortDescriptor = [NSSortDescriptor
sortDescriptorWithKey:@"firstName"
                    ascending:YES
                    selector:@selector(localizedStandardCompare:)];

NSSortDescriptor *lastNameSortDescriptor = [NSSortDescriptor sortDescriptorWithKey:@"lastName"
                    ascending:YES
                    selector:@selector(localizedStandardCompare:)];

NSSortDescriptor *ageSortDescriptor = [NSSortDescriptor sortDescriptorWithKey:@"age"
                    ascending:NO];

NSLog(@"By age: %@", [aryPerson sortedArrayUsingDescriptors:[ageSortDescriptor]]);
// "Charlie Smith", "Quentin Alberts", "Bob Jones", "Alice Smith"

NSLog(@"By first name: %@", [aryPerson
sortedArrayUsingDescriptors:[firstNameSortDescriptor]]);
// "Alice Smith", "Bob Jones", "Charlie Smith", "Quentin Alberts"

NSLog(@"By last name, first name: %@", [aryPerson
sortedArrayUsingDescriptors:[lastNameSortDescriptor, firstNameSortDescriptor]]);
// "Quentin Alberts", "Bob Jones", "Alice Smith", "Charlie Smith"
```

Read NSSortDescriptor online: <https://riptutorial.com/objective-c/topic/5833/nssortdescriptor>

Chapter 38: NSString

Introduction

The *NSString* class is a part of Foundation framework to work with strings (series of characters). It also includes methods for comparing, searching and modifying strings.

Remarks

For nesting various types of objects and data-types into NSStrings refer to: [Objective-C, Format Specifiers](#)

Examples

Creation

Simple:

```
NSString *newString = @"My String";
```

From multiple strings:

```
NSString *stringOne = @"Hello";
NSString *stringTwo = @"world";
NSString *newString = [NSString stringWithFormat:@"My message: %@ %@",
stringOne, stringTwo];
```

Using Mutable String

```
NSString *stringOne = @"Hello";
NSString *stringTwo = @"World";
NSMutableString *mutableString = [NSMutableString new];
[mutableString appendString:stringOne];
[mutableString appendString:stringTwo];
```

From NSData:

When initializing from *NSData*, an explicit encoding must be provided as *NSString* is not able to guess how characters are represented in the raw data stream. The most common encoding nowadays is UTF-8, which is even a requirement for certain data like JSON.

Avoid using `+[NSString stringWithUTF8String:]` since it expects an explicitly NULL-terminated C-string, which `-[NSData bytes]` does *not* provide.

```
NSString *newString = [[NSString alloc] initWithData:myData encoding:NSUTF8StringEncoding];
```

From NSArray:

```
NSArray *myArray = [NSArray arrayWithObjects:@"Apple", @"Banana", @"Strawberry", @"Kiwi",
nil];
NSString *newString = [myArray componentsJoinedByString:@" "];
```

String Length

NSString has a `length` property to get the number of characters.

```
NSString *string = @"example";
NSUInteger length = string.length; // length equals 7
```

As in the [Splitting Example](#), keep in mind that `NSString` uses **UTF-16** to represent characters. The `length` is actually just the number of UTF-16 code units. This can differ from what the user perceives as characters.

Here are some cases that might be surprising:

```
@ "é".length == 1 // LATIN SMALL LETTER E WITH ACUTE (U+00E9)
@ "é".length == 2 // LATIN SMALL LETTER E (U+0065) + COMBINING ACUTE ACCENT (U+0301)
@ "❤️".length == 2 // HEAVY BLACK HEART (U+2764) + VARIATION SELECTOR-16 (U+FE0F)
@ "🇹🇹".length == 4 // REGIONAL INDICATOR SYMBOL LETTER I (U+1F1EE) + REGIONAL INDICATOR SYMBOL
LETTER T (U+1F1F9)
```

In order to get the number of user-perceived characters, known technically as "[grapheme clusters](#)", you must iterate over the string with `-enumerateSubstringsInRange:options:usingBlock:` and keep a count. This is demonstrated in [an answer by Nikolai Ruhe on Stack Overflow](#).

Changing Case

To convert a String to uppercase, use `uppercaseString`:

```
NSString *myString = @"Emphasize this";
NSLog(@"%@", [myString uppercaseString]); // @"EMPHASIZE THIS"
```

To convert a String to lowercase, use `lowercaseString`:

```
NSString *myString = @"NORMALIZE this";
NSLog(@"%@", [myString lowercaseString]); // @"normalize this"
```

To capitalize the first letter character of each word in a string, use `capitalizedString`:

```
NSString *myString = @"firstname lastname";
NSLog(@"%@", [myString capitalizedString]); // @"Firstname Lastname"
```

Comparing Strings

Strings are compared for equality using `isEqualToString`:

The `==` operator just tests for object identity and does not compare the logical values of objects, so it can't be used:

```
NSString *stringOne = @"example";
NSString *stringTwo = [stringOne mutableCopy];

BOOL objectsAreIdentical = (stringOne == stringTwo);           // NO
BOOL stringsAreEqual = [stringOne isEqualToString:stringTwo]; // YES
```

The expression `(stringOne == stringTwo)` tests to see if the memory addresses of the two strings are the same, which is usually not what we want.

If the string variables can be `nil` you have to take care about this case as well:

```
BOOL equalValues = stringOne == stringTwo || [stringOne isEqualToString:stringTwo];
```

This condition returns `YES` when strings have equal values or both are `nil`.

To order two strings alphabetically, use `compare:..`

```
NSComparisonResult result = [firstString compare:secondString];
```

`NSComparisonResult` can be:

- `NSOrderedAscending`: The first string comes before the second string.
- `NSOrderedSame`: The strings are equal.
- `NSOrderedDescending`: The second string comes before the first string.

To compare two strings equality, use `isEqualToString:..`

```
BOOL result = [firstString isEqualToString:secondString];
```

To compare with the empty string (`@""`), better use `length`.

```
BOOL result = string.length == 0;
```

Joining an Array of Strings

To combine an `NSArray` of `NSString` into a new `NSString`:

```
NSArray *yourWords = @[@"Objective-C", @"is", @"just", @"awesome"];
NSString *sentence = [yourWords componentsJoinedByString:@" "];

// Sentence is now: @"Objective-C is just awesome"
```

Encoding and Decoding

```
// decode
NSString *string = [[NSString alloc] initWithData:utf8Data
```

```
encoding:NSUTF8StringEncoding];

// encode
NSData *utf8Data = [string dataUsingEncoding:NSUTF8StringEncoding];
```

Some supported encodings are:

- `NSASCIIStringEncoding`
- `:NSUTF8StringEncoding`
- `NSUTF16StringEncoding` (`== NSUnicodeStringEncoding`)

Note that `utf8Data.bytes` does not include a terminating null character, which is necessary for C strings. If you need a C string, use `UTF8String`:

```
const char *cString = [string UTF8String];
printf("%s", cString);
```

Splitting

You can split a string into an array of parts, divided by a **separator character**.

```
NSString * yourString = @"Stack,Exchange,Network";
NSArray * yourWords = [yourString componentsSeparatedByString:@","];
// Output: @[@"Stack", @"Exchange", @"Network"]
```

If you need to split on a set of **several different delimiters**, use `-[NSString componentsSeparatedByCharactersInSet:]`.

```
NSString * yourString = @"Stack Overflow+Documentation/Objective-C";
NSArray * yourWords = [yourString componentsSeparatedByCharactersInSet:
    [NSCharacterSet characterSetWithCharactersInString:@"+/"]];
// Output: @[@"Stack Overflow", @"Documentation", @"Objective-C"]`
```

If you need to break a string into its **individual characters**, loop over the length of the string and convert each character into a new string.

```
NSMutableArray * characters = [[NSMutableArray alloc] initWithCapacity:[yourString length]];
for (int i = 0; i < [myString length]; i++) {
    [characters addObject: [NSString stringWithFormat:@"%C",
        [yourString characterAtIndex:i]]];
}
```

As in the [Length Example](#), keep in mind that a "character" here is a UTF-16 code unit, not necessarily what the user sees as a character. If you use this loop with `@"🐶"`, you'll see that it's split into four pieces.

In order to get a list of the user-perceived characters, use `-[NSString enumerateSubstringsInRange:options:usingBlock:]`.

```

NSMutableArray * characters = [NSMutableArray array];
[yourString enumerateSubstringsInRange:NSMakeRange(0, [yourString length])
                    options:NSStringEnumerationByComposedCharacterSequences
                    usingBlock:^(NSString * substring, NSRange r, NSRange s, BOOL *
b){
                    [characters addObject:substring];
                }];

```

This preserves [grapheme clusters](#) like the Italian flag as a single substring.

Searching for a Substring

To search if a String contains a substring, do the following:

```

NSString *myString = @"This is for checking substrings";
NSString *subString = @"checking";

BOOL doesContainSubstring = [myString containsString:subString]; // YES

```

If targeting iOS 7 or OS X 10.9 (or earlier):

```

BOOL doesContainSubstring = ([myString rangeOfString:subString].location != NSNotFound); // YES

```

Working with C Strings

To convert NSString to const char use `-[NSString UTF8String]:`

```

NSString *myNSString = @"Some string";
const char *cString = [myNSString UTF8String];

```

You could also use `-[NSString cStringUsingEncoding:]` if your string is encoded with something other than UTF-8.

For the reverse path use `-[NSString stringWithUTF8String:]`:

```

const *char cString = "Some string";
NSString *myNSString = [NSString stringWithUTF8String:cString];
myNSString = @(cString); // Equivalent to the above.

```

Once you have the `const char *`, you can work with it similarly to an array of `chars`:

```

printf("%c\n", cString[5]);

```

If you want to modify the string, make a copy:

```

char *cpy = calloc(strlen(cString)+1, 1);
strncpy(cpy, cString, strlen(cString));
// Do stuff with cpy
free(cpy);

```

Removing Leading and Trailing Whitespace

```
NSString *someString = @" Objective-C Language \n";
NSString *trimmedString = [someString stringByTrimmingCharactersInSet:[NSCharacterSet
whitespaceAndNewlineCharacterSet]];
//Output will be - "Objective-C Language"
```

Method `stringByTrimmingCharactersInSet` returns a new string made by removing from both ends of the String characters contained in a given character set.

We can also just remove only whitespace or newline

```
// Removing only WhiteSpace
NSString *trimmedWhiteSpace = [someString stringByTrimmingCharactersInSet:[NSCharacterSet
whitespaceCharacterSet]];
//Output will be - "Objective-C Language \n"

// Removing only NewLine
NSString *trimmedNewLine = [someString stringByTrimmingCharactersInSet:[NSCharacterSet
newlineCharacterSet]];
//Output will be - " Objective-C Language "
```

Formatting

The `NSString` formatting supports all the format strings available on the `printf` ANSI-C function. The only addition made by the language is the `%%` symbol used for formatting all the Objective-C objects.

It is possible to format integers

```
int myAge = 21;
NSString *formattedAge = [NSString stringWithFormat:@"I am %d years old", my_age];
```

Or any object subclassed from `NSObject`

```
NSDate *now = [NSDate date];
NSString *formattedDate = [NSString stringWithFormat:@"The time right now is: %@", now];
```

For a complete list of Format Specifiers, please see: [Objective-C, Format Specifiers, Syntax](#)

Reversing a NSString Objective-C

```
// myString is "hi"
NSMutableString *reversedString = [NSMutableString string];
NSInteger charIndex = [myString length];
while (charIndex > 0) {
    charIndex--;
    NSRange subStrRange = NSMakeRange(charIndex, 1);
    [reversedString appendString:[myString substringWithRange:subStrRange]];
}
```

```
NSLog(@"%@", reversedString); // outputs "ih"
```

Read NSString online: <https://riptutorial.com/objective-c/topic/832/NSString>

Chapter 39: NSTextAttachment

Syntax

1. `NSTextAttachment *attachmentName = [[NSTextAttachment alloc] init];`

Remarks

`NSTextAttachment` objects are used by the `NSAttributedString` class cluster as the values for attachment attributes. The objects you create with this class are referred to as text attachment objects, or when no confusion will result, as text attachments or merely attachments.

Examples

NSTextAttachment Example

```
NSTextAttachment *attachment = [[NSTextAttachment alloc] init];
attachment.image = [UIImage imageNamed:@"imageName"];
attachment.bounds = CGRectMake(0, 0, 35, 35);
NSAttributedString *attachmentString = [NSAttributedString
attributedStringWithAttachment:attachment];
```

Read `NSTextAttachment` online: <https://riptutorial.com/objective-c/topic/7143/nstextattachment>

Chapter 40: NSTimer

Examples

Creating a Timer

This will create a timer to call the `doSomething` method on `self` in 5.0 seconds.

```
[NSTimer scheduledTimerWithTimeInterval:5.0
    target:self
    selector:@selector(doSomething)
    userInfo:nil
    repeats:NO];
```

Setting the `repeats` parameter to `false/NO` indicates that we want the timer to fire only once. If we set this to `true/YES`, it would fire every five seconds until manually invalidated.

Invalidating a timer

```
[timer invalidate];
timer = nil;
```

This will stop the timer from firing. **Must be called from the thread the timer was created in**, see [Apple's notes](#):

You must send this message from the thread on which the timer was installed. If you send this message from another thread, the input source associated with the timer may not be removed from its run loop, which could prevent the thread from exiting properly.

Setting `nil` will help you next to check whether it's running or not.

```
if(timer) {
    [timer invalidate];
    timer = nil;
}

//Now set a timer again.
```

Manually firing a timer

```
[timer fire];
```

Calling the `fire` method causes an `NSTimer` to perform the task it would have usually performed on a schedule.

In a **non-repeating timer**, this will automatically invalidate the timer. That is, calling `fire` before the time interval is up will result in only one invocation.

In a **repeating timer**, this will simply invoke the action without interrupting the usual schedule.

Storing information in the Timer

When creating a timer, you can set the `userInfo` parameter to include information that you want to pass to the function you call with the timer.

By taking a timer as a parameter in said function, you can access the `userInfo` property.

```
NSMutableDictionary *dictionary = @{
    @"Message" : @"Hello, world!"
}; //this dictionary contains a message

[NSTimer scheduledTimerWithTimeInterval:5.0
 target:self
 selector:@selector(doSomething)
 userInfo:dictionary
 repeats:NO]; //the timer contains the dictionary and later calls the function

...

- (void) doSomething:(NSTimer*)timer{
    //the function retrieves the message from the timer
    NSLog(@"%@", timer.userInfo[@"Message"]);
}
```

Read NSTimer online: <https://riptutorial.com/objective-c/topic/3773/nstimer>

Chapter 41: NSURL

Examples

Create

From NSString:

```
NSString *urlString = @"https://www.stackoverflow.com";
NSURL *myUrl = [NSURL URLWithString: urlString];
```

You can also use the following methods:

```
- initWithString:
+ URLWithString:relativeToURL:
- initWithString:relativeToURL:
+ fileURLWithPath:isDirectory:
- initWithFileURLWithPath:isDirectory:
+ fileURLWithPath:
- initWithFileURLWithPath:
    Designated_INITIALIZER
+ fileURLWithPathComponents:
+ URLByResolvingAliasFileAtURL:options:error:
+ URLByResolvingBookmarkData:options:relativeToURL:bookmarkDataIsStale:error:
- initWithResolvingBookmarkData:options:relativeToURL:bookmarkDataIsStale:error:
+ fileURLWithFileSystemRepresentation:isDirectory:relativeToURL:
- getFileSystemRepresentation:maxLength:
- initWithFileURLWithFileSystemRepresentation:isDirectory:relativeToURL:
```

Compare NSURL

```
NSString *urlString = @"https://www.stackoverflow.com";

NSURL *myUrl = [NSURL URLWithString: urlString];
NSURL *myUrl2 = [NSURL URLWithString: urlString];

if ([myUrl isEqual:myUrl2]) return YES;
```

Modifying and Converting a File URL with removing and appending path

1. URLByDeletingPathExtension:

If the receiver represents the root path, this property contains a copy of the original URL. If the URL has multiple path extensions, only the last one is removed.

2. URLByAppendingPathExtension:

Returns a new URL made by appending a path extension to the original URL.

Example:

```

    NSInteger count = 0;
    NSString *filePath = nil;
    do {
        NSString *extension = ( NSString *)UTTypeCopyPreferredTagWithClass((
        CFStringRef)AVFileTypeQuickTimeMovie, kUTTagClassFilenameExtension);
        NSString *fileNameNoExtension = [[asset.defaultRepresentation.url
        URLByDeletingPathExtension] lastPathComponent]; //Delete is used
        NSString *fileName = [NSString stringWithFormat:@"%d-%d-%d", fileNameNoExtension ,
        AVAssetExportPresetLowQuality, count];
        filePath = NSTemporaryDirectory();
        filePath = [filePath stringByAppendingPathComponent:fileName]; //Appending is used
        filePath = [filePath stringByAppendingPathExtension:extension];
        count++;

    } while ([[NSFileManager defaultManager] fileExistsAtPath:filePath]);

    NSURL *outputURL = [NSURL fileURLWithPath:filePath];

```

Read NSURL online: <https://riptutorial.com/objective-c/topic/1187/nsurl>

Chapter 42: NSURL send a post request

Examples

Simple POST request

```
// Create the request.
NSMutableURLRequest *request = [NSMutableURLRequest requestWithURL:[NSURL
URLWithString:@"http://google.com"]];

// Specify that it will be a POST request
request.HTTPMethod = @"POST";

// This is how we set header fields
[request setValue:@"application/xml; charset=utf-8" forHTTPHeaderField:@"Content-Type"];

// Convert your data and set your request's HTTPBody property
NSString *stringData = @"some data";
NSData *requestBodyData = [stringData dataUsingEncoding:NSUTF8StringEncoding];
request.HTTPBody = requestBodyData;

// Create url connection and fire request
NSURLConnection *conn = [[NSURLConnection alloc] initWithRequest:request delegate:self];
```

Simple Post Request With Timeout

```
// Create the request.
NSMutableURLRequest *request = [NSMutableURLRequest requestWithURL:[NSURL
URLWithString:@"http://google.com"]];

// Specify that it will be a POST request
request.HTTPMethod = @"POST";

// Setting a timeout
request.timeoutInterval = 20.0;
// This is how we set header fields
[request setValue:@"application/xml; charset=utf-8" forHTTPHeaderField:@"Content-Type"];

// Convert your data and set your request's HTTPBody property
NSString *stringData = @"some data";
NSData *requestBodyData = [stringData dataUsingEncoding:NSUTF8StringEncoding];
request.HTTPBody = requestBodyData;

// Create url connection and fire request
NSURLConnection *conn = [[NSURLConnection alloc] initWithRequest:request delegate:self];
```

Read NSURL send a post request online: <https://riptutorial.com/objective-c/topic/7243/nsurl-send-a-post-request>

Chapter 43: NSUserDefaults

Examples

Simple example

For example:

FOR SAVING:

```
NSUserDefaults *prefs = [NSUserDefaults standardUserDefaults];

// saving an NSString
[prefs setObject:txtUsername.text forKey:@"userName"];
[prefs setObject:txtPassword.text forKey:@"password"];

[prefs synchronize];
```

FOR RETRIEVING

```
NSUserDefaults *prefs = [NSUserDefaults standardUserDefaults];

// getting an NSString
NSString *savedUsername = [prefs stringForKey:@"userName"];
NSString *savedPassword = [prefs stringForKey:@"password"];
```

Clear NSUserDefaults

```
NSString *appDomain = [[NSBundle mainBundle] bundleIdentifier];
[[NSUserDefaults standardUserDefaults] removePersistentDomainForName:appDomain];
```

Read NSUserDefaults online: <https://riptutorial.com/objective-c/topic/10713/nsuserdefaults>

Chapter 44: Predefined Macros

Introduction

ANSI C defines a number of macros. Although each one is available for your use in programming, the predefined macros should not be directly modified.

Syntax

1. **DATE** The current date as a character literal in "MMM DD YYYY" format
2. **TIME** The current time as a character literal in "HH:MM:SS" format
3. **FILE** This contains the current filename as a string literal.
4. **LINE** This contains the current line number as a decimal constant.
5. **STDC** Defined as 1 when the compiler complies with the ANSI standard.

Examples

Predefined Macros

```
#import <Foundation/Foundation.h>

int main()
{
    NSLog(@"File :%s\n", __FILE__ );
    NSLog(@"Date :%s\n", __DATE__ );
    NSLog(@"Time :%s\n", __TIME__ );
    NSLog(@"Line :%d\n", __LINE__ );
    NSLog(@"ANSI :%d\n", __STDC__ );

    return 0;
}
```

When the above code in a file main.m is compiled and executed, it produces the following result:

```
2013-09-14 04:46:14.859 demo[20683] File :main.m
2013-09-14 04:46:14.859 demo[20683] Date :Sep 14 2013
2013-09-14 04:46:14.859 demo[20683] Time :04:46:14
2013-09-14 04:46:14.859 demo[20683] Line :8
2013-09-14 04:46:14.859 demo[20683] ANSI :1
```

Read Predefined Macros online: <https://riptutorial.com/objective-c/topic/8254/predefined-macros>

Chapter 45: Properties

Syntax

- `@property (optional_attributes, ...) type identifier`;
- `@synthesize identifier = optional_backing_ivar`;
- `@dynamic identifier`;

Parameters

Attribute	Description
<code>atomic</code>	<i>Implicit.</i> Enables synchronization in synthesized accessor methods.
<code>nonatomic</code>	Disables synchronization in the synthesized accessor methods.
<code>readwrite</code>	<i>Implicit.</i> Synthesizes getter, setter and backing ivar.
<code>readonly</code>	Synthesizes only the getter method and backing ivar, which can be assigned directly.
<code>getter=<i>name</i></code>	Specifies the name of getter method, implicit is <code>propertyName</code> .
<code>setter=<i>name</i></code>	Specifies the name of setter method, implicit is <code>setPropertyName:</code> . Colon : must be a part of the name.
<code>strong</code>	<i>Implicit for objects under ARC.</i> The backing ivar is synthesized using <code>__strong</code> , which prevents deallocation of referenced object.
<code>retain</code>	Synonym for <code>strong</code> .
<code>copy</code>	Same as <code>strong</code> , but the synthesized setter also calls <code>-copy</code> on the new value.
<code>unsafe_unretained</code>	<i>Implicit, except for objects under ARC.</i> The backing ivar is synthesized using <code>__unsafe_unretained</code> , which (for objects) results in dangling pointer once the referenced object deallocates.
<code>assign</code>	Synonym for <code>unsafe_unretained</code> . Suitable for non-object types.
<code>weak</code>	Backing ivar is synthesized using <code>__weak</code> , so the value will be nullified once the referenced object is deallocated.
<code>class</code>	Property accessors are synthesized as class methods, instead of instance methods. No backing storage is synthesized.
<code>nullable</code>	The property accepts <code>nil</code> values. Mainly used for Swift bridging.

Attribute	Description
<code>nonnull</code>	The property doesn't accept <code>nil</code> values. Mainly used for Swift bridging.
<code>null_resettable</code>	The property accepts <code>nil</code> values in setter, but never returns <code>nil</code> values from getter. Your custom implementation of getter or setter must ensure this behavior. Mainly used for Swift bridging.
<code>null_unspecified</code>	<i>Implicit.</i> The property doesn't specify handling of <code>nil</code> values. Mainly used for Swift bridging.

Examples

What are properties?

Here is an example class which has a couple of instance variables, without using properties:

```
@interface TestClass : NSObject {
    NSString *_someString;
    int _someInt;
}

-(NSString *)someString;
-(void)setSomeString:(NSString *)newString;

-(int)someInt;
-(void)setSomeInt:(NSString *)newInt;

@end

@implementation TestClass

-(NSString *)someString {
    return _someString;
}

-(void)setSomeString:(NSString *)newString {
    _someString = newString;
}

-(int)someInt {
    return _someInt;
}

-(void)setSomeInt:(int)newInt {
    _someInt = newInt;
}

@end
```

This is quite a lot of boilerplate code to create a simple instance variable. You have to create the instance variable & create accessor methods which do nothing except set or return the instance variable. So with Objective-C 2.0, Apple introduced properties, which auto-generate some or all of

the boilerplate code.

Here is the above class rewritten with properties:

```
@interface TestClass

@property NSString *someString;
@property int someInt;

@end

@implementation testClass

@end
```

A property is an instance variable paired with auto-generated getters and setters. For a property called `someString`, the getter and setter are called `someString` and `setSomeString` respectively. The name of the instance variable is, by default, the name of the property prefixed with an underscore (so the instance variable for `someString` is called `_someString`, but this can be overridden with an `@synthesize` directive in the `@implementation` section:

```
@synthesize someString=foo;    //names the instance variable "foo"
@synthesize someString;       //names it "someString"
@synthesize someString=_someString;    //names it "_someString"; the default if
                                      //there is no @synthesize directive
```

Properties can be accessed by calling the getters and setters:

```
[testObject setSomeString:@"Foo"];
NSLog(@"someInt is %d", [testObject someInt]);
```

They can also be accessed using dot notation:

```
testObject.someString = @"Foo";
NSLog(@"someInt is %d", testObject.someInt);
```

Custom getters and setters

The default property getters and setters can be overridden:

```
@interface TestClass

@property NSString *someString;

@end

@implementation TestClass

// override the setter to print a message
- (void)setSomeString:(NSString *)newString {
    NSLog(@"Setting someString to %@", newString);
    // Make sure to access the ivar (default is the property name with a _
```

```

    // at the beginning) because calling self.someString would call the same
    // method again leading to an infinite recursion
    _someString = newString;
}

- (void)doSomething {
    // The next line will call the setSomeString: method
    self.someString = @"Test";
}

@end

```

This can be useful to provide, for example, lazy initialization (by overriding the getter to set the initial value if it has not yet been set):

```

- (NSString *)someString {
    if (_someString == nil) {
        _someString = [self getInitialValueForSomeString];
    }
    return _someString;
}

```

You can also make a property that computes its value in the getter:

```

@interface Circle : NSObject

@property CGPoint origin;
@property CGFloat radius;
@property (readonly) CGFloat area;

@end

@implementation Circle

- (CGFloat)area {
    return M_PI * pow(self.radius, 2);
}

@end

```

Properties that cause updates

This object, `Shape` has a property `image` that depends on `numberOfSides` and `sideWidth`. If either one of them is set, then the `image` has to be recalculated. But recalculation is presumably long, and only needs to be done once if both properties are set, so the `Shape` provides a way to set both properties and only recalculate once. This is done by setting the property ivars directly.

In `Shape.h`

```

@interface Shape {
    NSUInteger numberOfSides;
    CGFloat sideWidth;

    UIImage * image;
}

```

```

// Initializer that takes initial values for the properties.
- (instancetype)initWithNumberOfSides:(NSUInteger)numberOfSides withWidth:(CGFloat)width;

// Method that allows to set both properties in once call.
// This is useful if setting these properties has expensive side-effects.
// Using a method to set both values at once allows you to have the side-
// effect executed only once.
- (void)setNumberOfSides:(NSUInteger)numberOfSides andWidth:(CGFloat)width;

// Properties using default attributes.
@property NSUInteger numberOfSides;
@property CGFloat sideWidth;

// Property using explicit attributes.
@property(strong, readonly) UIImage * image;

@end

```

In Shape.m

```

@implementation AnObject

// The variable name of a property that is auto-generated by the compiler
// defaults to being the property name prefixed with an underscore, for
// example "_propertyName". You can change this default variable name using
// the following statement:
// @synthesize propertyName = customVariableName;

- (id)initWithNumberOfSides:(NSUInteger)numberOfSides withWidth:(CGFloat)width {
    if ((self = [self init])) {
        [self setNumberOfSides:numberOfSides andWidth:width];
    }

    return self;
}

- (void)setNumberOfSides:(NSUInteger)numberOfSides {
    _numberOfSides = numberOfSides;

    [self updateImage];
}

- (void)setSideWidth:(CGFloat)sideWidth {
    _sideWidth = sideWidth;

    [self updateImage];
}

- (void)setNumberOfSides:(NSUInteger)numberOfSides andWidth:(CGFloat)sideWidth {
    _numberOfSides = numberOfSides;
    _sideWidth = sideWidth;

    [self updateImage];
}

// Method that does some post-processing once either of the properties has
// been updated.
- (void)updateImage {
    ...
}

```

```
}  
  
@end
```

When properties are assigned to (using `object.property = value`), the setter method `setProperty:` is called. This setter, even if provided by `@synthesize`, can be overridden, as it is in this case for `numberOfSides` and `sideWidth`. However, if you set an property's ivar directly (through `property` if the object is self, or `object->property`), it doesn't call the getter or setter, allowing you to do things like multiple property sets that only call one update or bypass side-effects caused by the setter.

Read Properties online: <https://riptutorial.com/objective-c/topic/1818/properties>

Chapter 46: Protocols

Examples

Basic Protocol Definition

Defining a new protocol:

```
@protocol NewProtocol
- (void)protocolMethod:(id)argument;
- (id)anotherMethod;
@end
```

Optional and required methods

By default, all the methods declared in a protocol are required. This means that any class that conforms to this protocol must implement those methods.

It is also possible to declare *optional* methods. These method can be implemented only if needed.

You mark optional methods with the `@optional` directive.

```
@protocol NewProtocol
- (void)protocolMethod:(id)argument;
@optional
- (id)anotherMethod;
@end
```

In this case, only `anotherMethod` is marked as optional; the methods without the `@optional` directive are assumed to be required.

The `@optional` directive applies to methods that follow, until the end of the protocol definition or, until another directive is found.

```
@protocol NewProtocol
- (void)protocolMethod:(id)argument;
@optional
- (id)anotherMethod;
- (void)andAnotherMethod:(id)argument;
@required
- (void)lastProtocolMethod;
@end
```

This last example defines a protocol with two optional methods and two required methods.

Conforming to Protocols

The following syntax indicate that a class adopts a protocol, using angle brackets.

```
@interface NewClass : NSObject <NewProtocol>
...
@end
```

This means that any instance of NewClass will respond to methods declared in its interface but also it will provide an implementation for all the required methods of NewProtocol.

It is also possible for a class to conform to multiple protocols, by separating them with comma.

```
@interface NewClass : NSObject <NewProtocol, AnotherProtocol, MyProtocol>
...
@end
```

Like when conforming to a single protocol, the class must implement each required method of each protocols, and each optional method you choose to implement.

Forward Declarations

It's possible to declare protocol name without methods:

```
@protocol Person;
```

use it your code (class definition, etc):

```
@interface World : NSObject
@property (strong, nonatomic) NSArray<id<some>> *employees;
@end
```

and later define protocol's method somewhere in your code:

```
@protocol Person
- (NSString *)gender;
- (NSString *)name;
@end
```

It's useful when you don't need to know protocols details until you import that file with protocol definition. So, your class header file stays clear and contains details of the class only.

Checking existence of optional method implementations

```
if ([object respondsToSelector:@selector(someOptionalMethodInProtocol)])
{
    [object someOptionalMethodInProtocol:argument];
}
```

Check conforms Protocol

Returns a Boolean indicating if the class conform the protocol:

```
[MyClass conformsToProtocol:@protocol(MyProtocol)];
```

Read Protocols online: <https://riptutorial.com/objective-c/topic/448/protocols>

Chapter 47: Protocols and Delegates

Remarks

Protocols and *Delegates* are two related but different concept:

A *Protocol* is a interface a class can conforms to, meaning that class implements the listed methods.

A *Delegate* is typically an anonymous object that conforms to a protocol.

The application of *Delegate* called *Delegation* is a design pattern.

At one end we have the concept of *Inheritance* which creates a tight coupling between the subclass and its superclass whereas *Delegation* design pattern provides an alternative to avoid this tight coupling using which we can create a much looser relationship based on anonymous *Delegate* objects.

Examples

Implementation of Protocols and Delegation mechanism.

Suppose you have two views `ViewA` and `ViewB`

Instance of `ViewB` is created inside `ViewA`, so `ViewA` can send message to `ViewB`'s instance, but for the reverse to happen we need to implement delegation (so that using delegate `ViewB`'s instance could send message to `ViewA`)

Follow these steps to implement the delegation

1. In `ViewB` create protocol as

```
@protocol ViewBDelegate

-(void) exampleDelegateMethod;

@end
```

2. Declare the delegate in the sender class

```
@interface ViewB : UIView
@property (nonatomic, weak) id< ViewBDelegate > delegate;
@end
```

3. Adopt the protocol in Class `ViewA`

```
@interfac ViewA: UIView < ViewBDelegate >
```

4. Set the delegate

```
-(void) anyFunction
{
    // create Class ViewB's instance and set the delegate
    [viewB setDelegate:self];
}
```

5. Implement the delegate method in class `ViewA`

```
-(void) exampleDelegateMethod
{
    // will be called by Class ViewB's instance
}
```

6. Use the method in class `ViewB` to call the delegate method as

```
-(void) callDelegateMethod
{
    [delegate exampleDelegateMethod];
    //assuming the delegate is assigned otherwise error
}
```

Read Protocols and Delegates online: <https://riptutorial.com/objective-c/topic/7832/protocols-and-delegates>

Chapter 48: Random Integer

Examples

Basic Random Integer

The `arc4random_uniform()` function is the simplest way to get high-quality random integers. As per the manual:

`arc4random_uniform(upper_bound)` will return a uniformly distributed random number less than `upper_bound`.

`arc4random_uniform()` is recommended over constructions like "`arc4random() % upper_bound`" as it avoids "modulo bias" when the upper bound is not a power of two.

```
uint32_t randomInteger = arc4random_uniform(5); // A random integer between 0 and 4
```

Random Integer within a Range

The following code demonstrates usage of `arc4random_uniform()` to generate a random integer between 3 and 12:

```
uint32_t randomIntegerWithinRange = arc4random_uniform(10) + 3; // A random integer between 3 and 12
```

This works to create a range because `arc4random_uniform(10)` returns an integer between 0 and 9. Adding 3 to this random integer produces a range between $0 + 3$ and $9 + 3$.

Read Random Integer online: <https://riptutorial.com/objective-c/topic/1573/random-integer>

Chapter 49: Singletons

Introduction

Just make sure you read this thread ([What is so bad about singletons?](#)) before using it.

Examples

Using Grand Central Dispatch (GCD)

GCD will guarantee that your singleton only gets instantiated once, even if called from multiple threads. Insert this into any class for a singleton instance called `shared`.

```
+ (instancetype)shared {  
  
    // Variable that will point to the singleton instance. The `static`  
    // modifier makes it behave like a global variable: the value assigned  
    // to it will "survive" the method call.  
    static id _shared;  
  
    static dispatch_once_t _onceToken;  
    dispatch_once(&_onceToken, ^{  
  
        // This block is only executed once, in a thread-safe way.  
        // Create the instance and assign it to the static variable.  
        _shared = [self new];  
    });  
  
    return _shared;  
}
```

Creating Singleton class and also preventing it from having multiple instances using alloc/init.

We can create Singleton class in such a way that developers are forced to use the shared instance (singleton object) instead of creating their own instances.

```
@implementation MySingletonClass  
  
+ (instancetype)sharedInstance  
{  
    static MySingletonClass *_sharedInstance = nil;  
    static dispatch_once_t oncePredicate;  
    dispatch_once(&oncePredicate, ^{  
        _sharedInstance = [[self alloc] initClass];  
    });  
  
    return _sharedInstance;  
}  
  
-(instancetype)initClass
```

```

{
    self = [super init];
    if(self)
    {
        //Do any additional initialization if required
    }
    return self;
}

- (instancetype)init
{
    @throw [NSException exceptionWithName:@"Not designated initializer"
                                         reason:@"Use [MySingletonClass sharedInstance]"
                                         userInfo:nil];

    return nil;
}
@end

/*Following line will throw an exception
with the Reason:"Use [MySingletonClass sharedInstance]"
when tried to alloc/init directly instead of using sharedInstance */
MySingletonClass *mySingletonClass = [[MySingletonClass alloc] init];

```

Creating Singleton and also preventing it from having multiple instance using alloc/init, new.

```

//MySingletonClass.h
@interface MySingletonClass : NSObject

+ (instancetype)sharedInstance;

-(instancetype)init NS_UNAVAILABLE;

-(instancetype)new NS_UNAVAILABLE;

@end

//MySingletonClass.m

@implementation MySingletonClass

+ (instancetype)sharedInstance
{
    static MySingletonClass *_sharedInstance = nil;
    static dispatch_once_t oncePredicate;
    dispatch_once(&oncePredicate, ^{
        _sharedInstance = [[self alloc] init];
    });

    return _sharedInstance;
}

-(instancetype)init
{
    self = [super init];
    if(self)
    {
        //Do any additional initialization if required
    }
}

```

```
    }  
    return self;  
}  
@end
```

Read Singletons online: <https://riptutorial.com/objective-c/topic/2834/singletons>

Chapter 50: Structs

Syntax

- `typedef struct { typeA propertyA; typeB propertyB; ... } StructName`

Remarks

In Objective C, you should almost always use an object instead of a struct. However, there are still cases where using a struct is better, such as:

- When you're going to be creating and destroying a lot of values of the (struct) type, so you need good performance and small memory usage
 - Structs are faster to create and use because when calling a method on an object, the method has to be determined at runtime
 - Structs take up less size because objects have an extra property `isa`, which holds their class
- When the value has only a couple of properties and a small total size (take `CGSize`; it has 2 floats which are 4 bytes each, so it can take up 8 bytes), and is going to be used a lot (ties in with the first point)
- When you could use [unions](#) or [bitfields](#), and importantly, *need the size saved by them* because you need small memory usage (ties in with the first point)
- When you *really* want to store an array inside of the struct, since Objective-C objects can't directly store C-arrays. However, note that you can still "indirectly" get an array in an Objective-C object by making it a reference (i.e. `type *` in place of the C-array `type[]`)
- When you need to communicate with some other code, such as a library, that's coded in C; structs are fully implemented in C but objects are not

Examples

CGPoint

One really good example of a struct is `CGPoint`; it's a simple value that represents a 2-dimensional point. It has 2 properties, `x` and `y`, and can be written as

```
typedef struct {
    CGFloat x;
    CGFloat y;
} CGPoint;
```

If you used Objective-C for Mac or iOS app development before, you've almost certainly come across `CGPoint`; `CGPoint`s hold the position of pretty much everything on screen, from views and controls to objects in a game to changes in a gradient. This means that `CGPoint`s are used a lot.

This is even more true with really performance-heavy games; these games tend to have a lot of objects, and all of these objects need positions. These positions are often either `CGPoint`s, or some other type of struct that conveys a point (such as a 3-dimensional point for 3d games).

Points like `CGPoint` could easily be represented as objects, like

```
@interface CGPoint {
    CGFloat x;
    CGFloat y;
}

... //Point-related methods (e.g. add, isEqualToPoint, etc.)

@property(nonatomic, assign)CGFloat x;
@property(nonatomic, assign)CGFloat y;

@end

@implementation CGPoint

@synthesize x, y;

...

@end
```

However, if `CGPoint` was used in this way it would take a lot longer to create and manipulate points. In smaller, faster programs this wouldn't really cause a difference, and in those cases it would be OK or maybe even better to use object points. But in large programs where points are be used a lot, using objects as points can really hurt performance, making the program slower, and also waste memory, which could force the program to crash.

Defining a Structure and Accessing Structure Members

The format of the struct statement is this:

```
struct [structure tag]
{
    member definition;
    member definition;
    ...
    member definition;
} [one or more structure variables];
```

Example: declare the `ThreeFloats` structure:

```
typedef struct {
    float x, y, z;
} ThreeFloats;

@interface MyClass
- (void)setThreeFloats:(ThreeFloats)threeFloats;
- (ThreeFloats)threeFloats;
```

```
@end
```

Sending an instance of MyClass the message valueForKey: with the parameter @"threeFloats" will invoke the MyClass method threeFloats and return the result wrapped in an NSValue.

Read Structs online: <https://riptutorial.com/objective-c/topic/3792/structs>

Chapter 51: Subscripting

Examples

Subscripts with NSArray

Subscripts can be used to simplify retrieving and setting elements in an array. Given the following array

```
NSArray *fruit = @[@"Apples", @"Bananas", @"Cherries"];
```

This line

```
[fruit objectAtIndex: 1];
```

Can be replaced by

```
fruit[1];
```

They can also be used to set an element in a mutable array.

```
NSMutableArray *fruit = [@[@"Apples", @"Bananas", @"Cherries"] mutableCopy];  
fruit[1] = @"Blueberries";  
NSLog(@"%@", fruit[1]); //Blueberries
```

If the index of the subscript equals the count of the array, the element will be appended to the array.

Repeated subscripts may be used to access elements of nested arrays.

```
NSArray *fruit = @[@"Apples", @"Bananas", @"Cherries"];  
NSArray *vegetables = @[@"Avocado", @"Beans", @"Carrots"];  
NSArray *produce = @[fruit, vegetables];  
  
NSLog(@"%@", produce[0][1]); //Bananas
```

Subscripts with NSDictionary

Subscripts can also be used with NSDictionary and NSMutableDictionary. The following code:

```
NSMutableDictionary *myDictionary = [:@{@"Foo": @"Bar"} mutableCopy];  
[myDictionary setObject:@"Baz" forKey:@"Foo"];  
NSLog(@"%@", [myDictionary objectForKey:@"Foo"]); // Baz
```

Can be shortened to:

```
NSMutableDictionary *myDictionary = [:@{@"Foo": @"Bar"} mutableCopy];  
myDictionary[@"Foo"] = @"Baz";  
NSLog(@"%@", myDictionary[@"Foo"]); // Baz
```

Custom Subscripting

You can add subscripting to your own classes by implementing the required methods.

For indexed subscripting (like arrays):

```
- (id)objectAtIndexedSubscript:(NSUInteger)idx  
- (void)setObject:(id)obj atIndexedSubscript:(NSUInteger)idx
```

For keyed subscripting (like dictionaries):

```
- (id)objectForKeyedSubscript:(id)key  
- (void)setObject:(id)obj forKeyedSubscript:(id <NSCopying>)key
```

Read Subscripting online: <https://riptutorial.com/objective-c/topic/3825/subscripting>

Chapter 52: Unit testing using Xcode

Remarks

Dependencies:

- If application uses third party libraries or cocoa pods, then those libraries or pods are needed to be install for test as well.
- Test class (Test Suit) extends XCTestCase.

Get brushed up before starting:

- All test classes have two methods in common setUp & tearDown.
- setUp runs before every testcase & tearDown after every testcase.
- Test cases runs alphabetically.
- In Test Driven Development, it is good to create dummy test data first.
- Test case methods starts with "test" keyword.
- Test methods accept no parameters & return no value.

Appendix:

There are several other methods for comparing the expected result & actual result out of an operation. Some of those methods are listed below:

- XCTAssertNil(expression, comment) generates a failure if expression != nil.
- XCTAssertNotNil(expression, comment) generates a failure if expression = nil.
- XCTAssert(expression, comment) generates a failure if expression == false.
- XCTAssertTrue(expression, comment) generates a failure if expression == false.
- XCTAssertFalse(expression, comment) generates a failure if expression != false.
- XCTAssertEqualObjects(expression1, expression2, comment) generates a failure if expression1 is not equal to expression2.
- XCTAssertEqualObjects(expression1, expression2, comment) generates a failure if expression1 is equal to expression2.
- XCTAssertNotEqual(expression1, expression2, comment) generates a failure if expression1 == expression2.
- XCTAssertEqual(expression1, expression2, comment) generates a failure if expression1 != expression2.
- XCTAssertGreaterThanOrEqual(expression1, expression2, comment) generates a failure when (expression1 < expression2).

Examples

Testing a block of code or some method:

- Import the class, which contains the method to be tested.
- Perform the operation with dummy data.
- Now compare the result of operation with expected result.

```
- (void)testReverseString{
NSString *originalString = @"hi_my_name_is_siddharth";
NSString *reversedString = [self.someObject reverseString:originalString];
NSString *expectedReversedString = @"htrahddis_si_eman_ym_ih";
XCTAssertEqualObjects(expectedReversedString, reversedString, @"The reversed string did not match the expected reverse");
}
```

Feed the dummy data to the method under test if required & then compare the expected & actual results.

Testing asynchronous block of code:

```
- (void)testDoSomethingThatTakesSomeTime{
XCTestExpectation *completionExpectation = [self expectationWithDescription:@"Long method"];
[self.someObject doSomethingThatTakesSomeTimesWithCompletionBlock:^(NSString *result) {
    XCTAssertEqualObjects(@"result", result, @"Result was not correct!");
    [completionExpectation fulfill];
}];
[self waitForExpectationsWithTimeout:5.0 handler:nil];
}
```

- Feed the dummy data to the method under test if required.
- The test will pause here, running the run loop, until the timeout is hit or all expectations are fulfilled.
- Timeout is the expected time for the asynchronous block to response.

Measuring Performance of a block of code:

1. For Synchronous methods :

```
- (void)testPerformanceReverseString {
    NSString *originalString = @"hi_my_name_is_siddharth";
    [self measureBlock:^(
        [self.someObject reverseString:originalString];
    )];
}
```

2. For Asynchronous methods :

```

- (void)testPerformanceOfAsynchronousBlock {
    [self measureMetrics:@[XCTPerformanceMetric_WallClockTime] automaticallyStartMeasuring:YES
    forBlock:^(
        XCTestExpectation *expectation = [self
    expectationWithDescription:@"performanceTestWithResponse"];

    [self.someObject doSomethingThatTakesSomeTimesWithCompletionBlock:^(NSString *result) {
        [expectation fulfill];
    }];
    [self waitForExpectationsWithTimeout:5.0 handler:^(NSError *error) {
    }];
    }];
}

```

- These performance measure block gets executed for 10 times consecutively & then the average is calculated, & on the basis of this average performance result gets created & baseline is accepted for further evaluation.
- The performance result is compared with the previous test results & baseline with a customizable max standard deviation.

Running Test Suits:

Run all tests by choosing Product > Test. Click the Test Navigator icon to view the status and results of the tests. You can add a test target to a project (or add a class to a test) by clicking the Add (plus) button in the bottom-left corner of the test navigator. To view the source code for a particular test, select it from the test list. The file opens in the source code editor.

Note:

Make sure that include unit test case box is checked when creating a new project as shown below:

Choose options for your new project:

Product Name:

Organization Name:

DMI

Organization Identifier:

com.DMI

Bundle Identifier:

com.DMI.ProductName

Language:

Chapter 53: XML parsing

Examples

XML Parsing

```
<?xml version="1.0" encoding="UTF-8"?>
<GeocodeResponse>
  <status>OK</status>
  <result>
    <type>premise</type>
    <formatted_address>4201 Oak Lawn Ave, Dallas, TX 75219, USA</formatted_address>
    <address_component>
      <long_name>4201</long_name>
      <short_name>4201</short_name>
      <type>street_number</type>
    </address_component>
    <address_component>
      <long_name>Oak Lawn Avenue</long_name>
      <short_name>Oak Lawn Ave</short_name>
      <type>route</type>
    </address_component>
    <address_component>
      <long_name>Oak Lawn</long_name>
      <short_name>Oak Lawn</short_name>
      <type>neighborhood</type>
      <type>political</type>
    </address_component>
    <address_component>
      <long_name>Dallas</long_name>
      <short_name>Dallas</short_name>
      <type>locality</type>
      <type>political</type>
    </address_component>
  </result>
</GeocodeResponse>
```

We will parse the highlighted tag data through `NSXMLParser`

We have declared few properties as follows

```
@property(nonatomic, strong)NSMutableArray *results;
@property(nonatomic, strong)NSMutableString *parsedString;
@property(nonatomic, strong)NSXMLParser *xmlParser;

//Fetch xml data
NSURLSession *session=[NSURLSession sessionWithConfiguration:[NSURLSessionConfiguration
```

```

defaultSessionConfiguration]];

NSURLSessionDataTask *task=[session dataTaskWithRequest:[NSURLRequest requestWithURL:[NSURL
URLWithString:YOUR_XMLURL]] completionHandler:^(NSData * _Nullable data, NSURLResponse *
_Nullable response, NSError * _Nullable error) {

self.xmlParser=[[NSXMLParser alloc] initWithData:data];
self.xmlParser.delegate=self;
if([self.xmlParser parse]){
    //If parsing completed successfully

        NSLog(@"%@",self.results);

}

}];

[task resume];

```

Then we define the `NSXMLParserDelegate`

```

- (void)parser:(NSXMLParser *)parser didStartElement:(NSString *)elementName
namespaceURI:(nullable NSString *)namespaceURI qualifiedName:(nullable NSString *)qName
attributes:(NSDictionary<NSString *, NSString *> *)attributeDict{

    if([elementName isEqualToString:@"GeocodeResponse"]){
        self.results=[[NSMutableArray alloc] init];
    }

    if([elementName isEqualToString:@"formatted_address"]){
        self.parsedString=[[NSMutableString alloc] init];
    }

}

- (void)parser:(NSXMLParser *)parser foundCharacters:(NSString *)string{

    if(self.parsedString){
        [self.parsedString appendString:[string
stringByTrimmingCharactersInSet:[NSCharacterSet whitespaceAndNewlineCharacterSet]]];
    }

}

- (void)parser:(NSXMLParser *)parser didEndElement:(NSString *)elementName
namespaceURI:(nullable NSString *)namespaceURI qualifiedName:(nullable NSString *)qName{

    if([elementName isEqualToString:@"formatted_address"]){
        [self.results addObject:self.parsedString];

        self.parsedString=nil;
    }

}

```
